The findings in this report are subject to at least three limitations. First, in the state-level analysis, rankings for four states (Maryland, Massachusetts, Rhode Island, and Utah) might have been affected by large proportions of injury deaths of undetermined intent (potentially biasing reported suicide rates downward) or decreased percentages of such deaths over time (potentially biasing estimated rate trends upward). Second, NVDRS is not yet nationally representative; the 27 states included represent 49.6% of the population (<https://factfinder.census.gov/faces/tableservices/jsf/pages/productview.xhtml>). Finally, abstractors of NVDRS data are limited to information contained in investigative reports. Therefore, the extent of informant knowledge can affect data completeness and accuracy. Studies that include more in-depth interviews with next-of-kin often identify greater attributions to mental disorders (13); however, many methodological variations across studies exist (14). It is likely that some persons without known mental health conditions in the current study were experiencing mental health challenges that were unknown, and

## References

## Summary

## What is already known about this topic?

In 2016, nearly 45,000 persons died by suicide in the United States. Mental health conditions ~~can contribute to suicide~~.

## What is added by this report?

During 1999–2016, suicide rates increased in nearly every state, including >30% increases in 25 states. 2015 data from 27 states indicate 54% of suicide decedents were not known to have mental health conditions. Other contributors included relationship, substance use, health, and job or financial problems, among others.

## What are the implications for public health practice?

A comprehensive approach using proven prevention strategies, such as those in CDC's Technical Package for Suicide Prevention, can help reach the national goal of reducing the annual suicide rate 20% by 2025.

hence underreported by key informants. Nonetheless, the high prevalence of diverse contributing circumstances among those with and without known mental health conditions suggests the importance of addressing the broad range of factors that contribute to suicide.

Suicide is a growing public health problem. Effective approaches to prevent the many suicide risk factors are available. States and communities can use data from NVDRS and resources such as CDC's Preventing Suicide: a Technical Package of Policy, Programs, and Practices (12) to better understand suicide in their populations, prioritize evidence-based comprehensive suicide prevention, and save lives.

### Abstract

**Introduction:** Suicide rates in the United States have risen nearly 30% since 1999, and mental health conditions are just one factor contributing to suicide. Examining state-level trends in suicide and the multiple circumstances contributing to it can inform comprehensive state suicide prevention planning.

**Methods:** Trends in age-adjusted suicide rates among persons aged  $\geq 10$  years, by state and sex, across six consecutive 3-year periods (1999–2016), were assessed using data from the National Vital Statistics System for 50 states and the District of Columbia. Data from the National Violent Death Reporting System, covering 27 states in 2015, were used to examine contributing circumstances among decedents with and without known mental health conditions.

**Results:** During 1999–2016, suicide rates increased significantly in 44 states, with 25 states experiencing increases  $>30\%$ . Rates increased significantly among males and females in 34 and 43 states, respectively. Fifty-four percent of decedents in 27 states in 2015 did not have a known mental health condition.

Among decedents with available information, several circumstances were significantly more likely among those without known mental health conditions than among those with mental health conditions, including relationship problems/loss (45.1% versus 39.6%), life stressors (54.2% versus 49.7%), and recent/impending crises (32.9% versus 26.0%), but these circumstances were common across groups.

**Conclusions:** Suicide rates increased significantly across most states during 1999–2016. Various circumstances contributed to suicides among persons with and without known mental health conditions.

**Implications for Public Health Practice:** States can use a comprehensive evidence-based public health approach to prevent suicide risk before it occurs, identify and support persons at risk, prevent reattempts, and help friends and family members in the aftermath of a suicide.

## Introduction

In 2016, nearly 45,000 suicides (15.6/100,000 population [age-adjusted]) occurred in the United States among persons aged  $\geq 10$  years (1). From 1999 to 2015, suicide rates increased among both sexes, all racial/ethnic groups, and all urbanization levels (2,3). Suicide rates have also increased among persons in all age groups  $< 75$  years, with the largest percent increase (45%; from 13.2 per 100,000 persons [1999] to 19.2 per 100,000 [2016]) and the greatest number of suicides (232,108 from 1999 to 2016) occurring among adults age 45–65 years (1,3). Suicide is the 10th leading cause of death and is one of just three leading causes that are increasing (1,4). In addition, rates of emergency department visits for nonfatal self-harm, a main risk factor for suicide, increased 42% from 2001 to 2016 (1). Together, suicides and self-harm injuries cost the nation approximately \$69 billion in direct medical and work loss costs (1).

The National Strategy for Suicide Prevention (NSSP) (5) calls for a public health approach to suicide prevention with efforts spanning multiple levels (individual, family/relationship, community, and societal). Such a comprehensive approach underscores that suicide is rarely caused by any single factor, but rather, is determined by multiple factors. Despite NSSP guidance, suicide prevention largely focuses on mental health conditions alone by identifying suicidal persons, providing treatment for mental health conditions, and preventing reattempts (6). In addition to mental health conditions and

prior suicide attempts, other contributing circumstances include social and economic problems, access to lethal means (e.g., substances, firearms) among persons at risk, and poor coping and problem-solving skills (5). Expanded awareness of these additional circumstances contributing to suicide risk and action to address them can help reach the national goal, established by the National Action Alliance of Suicide Prevention and the American Foundation for Suicide Prevention, of reducing the annual suicide rate 20% by 2025 (7). To assist states in achieving this goal, CDC analyzed state-specific trends in suicide rates and assessed the multiple contributing factors to suicide; this report presents options for multilevel comprehensive suicide prevention based on the best available evidence.

## Methods

Suicide rates were analyzed for persons aged  $\geq 10$  years because determining suicidal intent in younger children can be difficult (8). Age-specific suicide counts were tabulated based on National Vital Statistics System coded death certificate records (*International Classification of Diseases, Tenth Revision*, underlying-cause-of-death codes X60–X84, Y87.0, U03). Age-specific population estimates were obtained from U.S. Census Bureau/National Center for Health Statistics bridged-race population data releases.

National and state-level suicide rate estimates were calculated for six consecutive 3-year aggregate periods spanning 1999–2016 (1999–2001; 2002–2004; 2005–2007;

2008–2010; 2011–2013; and 2014–2016). Rate estimates were age-adjusted to the U.S. 2000 standard population and expressed per 100,000 persons per year. Age-adjusted suicide rate trends were modeled using the same 3-year data aggregates, employing weighted least-squares regression with inverse-variance weighting. Modeled rate trends are reported in terms of average annual percentage changes.

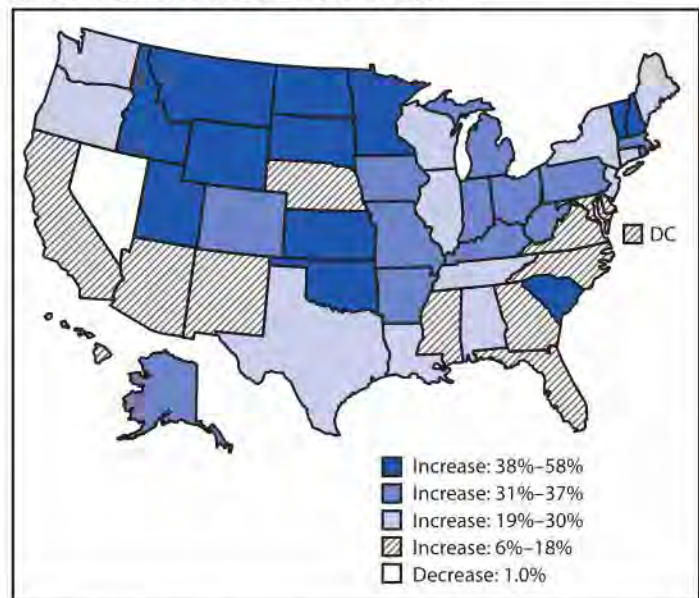

Characteristics of persons aged  $\geq 10$  years who died by suicide, with and without known mental health conditions, and the circumstances surrounding the suicides were compared in the 27 states\* with complete data participating in CDC's National Violent Death Reporting System (NVDRS) in 2015. NVDRS defines mental health conditions as disorders and syndromes listed in the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (9), with the exception of alcohol and other substance use disorders, which are captured separately in NVDRS. NVDRS aggregates data from three primary data sources: death certificates, coroner/medical examiner reports (including toxicology), and law enforcement reports. A range of circumstances (relationship problems, life stressors, and recent or impending crises) have been identified as potential risk factors for suicide. Circumstances captured by NVDRS are those identified by next of kin as having actively contributed to a person's suicide. Decedents could have experienced multiple circumstances. Decedents with and without known mental health conditions were compared using Chi-square tests. Logistic regression analyses estimated adjusted odds ratios (aORs) with 95% confidence intervals (CIs), controlling for age group, sex, and race/ethnicity.

## Results

The most recent overall suicide rates (representing 2014–2016) varied fourfold, from 6.9 (District of Columbia) to 29.2 (Montana) per 100,000 persons per year (Supplementary Table; <https://stacks.cdc.gov/view/cdc/53785>). Across the study period, rates increased in all states except Nevada (where the rate was consistently high throughout the study period), with absolute increases ranging from 0.8 per 100,000 (Delaware) to 8.1 (Wyoming). Percentage increases in rates ranged from 5.9% (Delaware) to 57.6% (North Dakota), with increases  $>30\%$  observed in 25 states (Supplementary Table; <https://stacks.cdc.gov/view/cdc/53785>) (Figure).

Modeled suicide rate trends indicated significant increases in 44 states, among males (34 states) and females (43 states), as well as for the United States overall (Supplementary Table; <https://stacks.cdc.gov/view/cdc/53785>). Nationally, the

**FIGURE. Percent change in annual suicide rate,\* by state — United States, from 1999–2001 to 2014–2016**

\* Per 100,000 population, age-adjusted to the 2000 U.S. standard population.

model-estimated average annual percentage change for the overall suicide rate was an increase of 1.5%. By sex, estimated national rate trends further indicated significant average annual percentage change increases for males (1.1%) and females (2.6%) (Supplementary Table; <https://stacks.cdc.gov/view/cdc/53785>).

Suicide decedents without known mental health conditions (11,039) were compared with those with known mental health conditions (9,407) in 27 states. Whereas all decedents were predominately male (76.8%) (Table 1) and non-Hispanic white (83.6%), those without known mental health conditions, relative to those with mental health conditions, were more likely to be male (83.6% versus 68.8%; odds ratio [OR] = 2.3, 95% CI = 2.2–2.5) and belong to a racial/ethnic minority (OR range = 1.2–2.0). Suicide decedents without known mental health conditions also had significantly higher odds of perpetrating homicide followed by suicide (aOR = 2.9, 95% CI = 2.2–3.8). Among adult decedents aged  $\geq 18$  years, 20.1% of those without known mental health conditions and 15.3% of those with mental health conditions had ever served in the U.S. military or were serving at the time of death.

Whereas firearms were the most common method of suicide overall (48.5%) and among decedents with and without mental health conditions, decedents without known mental health conditions, relative to those with known mental health conditions, were more likely to die by firearm (55.3% versus 40.6%) and less likely to die by hanging/strangulation/suffocation (26.9% versus 31.3%) or poisoning (10.4% versus 19.8%). These differences remained significant in the adjusted models.

See table footnotes on next page.

Toxicology testing was less likely to be performed for decedents without known mental health conditions. Among those with toxicology results, decedents without known mental health conditions were less likely to test positive for any substance overall (aOR = 0.8, 95% CI = 0.7–0.8), including opioids (aOR = 0.90, 95% CI = 0.81–0.99), but were more likely to test positive for alcohol (aOR = 1.2, 95% CI = 1.1–1.3).

Information on circumstances surrounding suicide were available for all decedents with mental health conditions (n = 9,407) and approximately 85% of those without known mental health conditions (n = 9,357) in 27 states (Table 2). Persons without known mental health conditions were less likely to have any substance use disorders (aOR = 0.7, 95% CI = 0.7–0.8) than were persons with known mental health conditions. Whereas two thirds of decedents with known mental health conditions had a history of mental health or substance use treatment (67.2%), just over half (54.0%) were in treatment at the time of death.

Decedents without known mental health conditions had a significantly higher likelihood of any relationship problem/loss (45.1%) than did those with known mental health conditions (39.6%), specifically intimate partner problems (30.2% versus 24.1%), arguments/conflicts (17.5% versus 13.6%), and perpetrating interpersonal violence in the past month (3.0% versus 1.4%). Decedents without known mental health conditions were also more likely than were those with known mental health conditions to have experienced any life stressors (54.2% versus 49.7%) such as criminal legal problems (10.7% versus 6.2%) or eviction/loss of home (4.3% versus 3.4%) and were more likely to have had a recent or impending (within the preceding or upcoming 2 weeks, respectively) crisis (a current or acute event thought to contribute to the suicide) (32.9% versus 26.0%). All of these differences remained significant in the adjusted models. Physical health problems and job/financial problems were commonly contributing stressors among both persons without mental health conditions (23.2% and

\* Alaska, Arizona, Colorado, Connecticut, Georgia, Hawaii, Kansas, Kentucky, Maine, Maryland, Massachusetts, Michigan, Minnesota, New Hampshire, New Jersey, New Mexico, New York, North Carolina, Ohio, Oklahoma, Oregon, Rhode Island, South Carolina, Utah, Vermont, Virginia, and Wisconsin.

† Decedent had been identified as having a current diagnosis of mental health condition in coroner/medical examiner or law enforcement reports.

§ OR reflects the risk among those without known mental health condition relative to those with known mental health condition.

¶ Logistic regression was used to estimate adjusted OR with 95% CIs after controlling for age, sex, race, and ethnicity. Known mental health condition was used as the reference group.

\*\* Decedents were aged ≥10 years, as per standard in the suicide prevention literature.

†† Denominator is decedents aged ≥18 years with reported military service status.

§§ Denominator is decedents who died by poisoning, including overdose.

¶¶ Denominator is decedents with any toxicology testing.

\*\*\* Denominator for each positive group is the number tested for the substance in that group.

15.6%, respectively) and those with mental health conditions (21.4% and 16.8%, respectively). Similarly, among all persons with recent crises, intimate partner problems were the most common types and did not differ by group.

Decedents without known mental health conditions had significantly lower odds of recent release from any institution (aOR = 0.5, 95% CI = 0.4–0.5). Among those recently released, decedents without known mental health conditions were significantly more likely than decedents with mental health problems to have been released from a correctional facility (25.7% versus 8.7%), hospital (43.7% versus 33.0%), or other facility, such as an alcohol/substance use treatment facility (24.2% versus 11.6%). Among decedents with known mental health conditions who were recently released from an institution, 46.7% were released from psychiatric facilities.

Decedents without known mental health conditions were significantly less likely to have a history of suicidal ideation

(23.0%) or prior suicide attempts (10.3%) compared with those with known mental health conditions (40.8% and 29.4%, respectively). Suicide intent was disclosed by 22.4% and 24.5% of persons without and with known mental health conditions, respectively.

## Conclusions and Comments

During 1999–2016, suicide rates increased significantly in 44 states, and 25 states experienced increases >30%. Rates increased significantly among males in 34 states, and females in 43 states. Additional research into the specific causes of these trends is needed. Data from the 27 states participating in NVDRS provide important insight into circumstances surrounding suicide and can help states identify prevention priorities.

Suicidologists regularly state that suicide is not caused by a single factor (5); however, suicide prevention is often

oriented toward mental health conditions alone with regard to downstream identification of suicidal persons, treatment of mental health conditions, and prevention of reattempts. This study found that approximately half of suicide decedents in NVDRS did not have a known mental health condition, indicating that additional focus on nonmental health factors further upstream could provide important information for a public health approach (10). Those without a known mental health condition suffered more from relationship problems and other life stressors such as criminal/legal matters, eviction/loss of home, and recent or impending crises.

Similarly, persons with mental health conditions also often experienced nonmental health factors such as relationship problems and other life stressors such as job/financial or physical health problems. These findings point to the need to both prevent the circumstances associated with the onset of mental health conditions in the first place and support persons with known mental health conditions to decrease their risk for poor outcomes (11). Two thirds of suicide decedents with mental health conditions had a history of treatment for mental health or substance use disorders, with approximately half in treatment when they died. This finding suggests the need for additional safety supports, including broader implementation

\*\*\* Denominator of institution subgroup is decedents with recent release from an institution. Recent release from an institution is defined as having occurred within the past month.

<sup>†††</sup> Denominator of crisis subgroup is decedents with any crisis within past or upcoming 2 weeks. Crises depicted here represent the most commonly occurring categories.

of affordable and effective treatment modalities, such as doctor-patient collaborative care models and proven cognitive-behavioral therapies. In addition, increased access to behavioral health providers in underserved areas is needed, as is expansion of health care systems that integrate physical and behavioral health, with a priority on suicide prevention and patient safety, especially through care transitions (12).

Comprehensive statewide suicide prevention activities are needed to address the full range of factors contributing to suicide. Prevention strategies include strengthening economic supports (e.g., housing stabilization policies, household financial support); teaching coping and problem-solving skills to manage everyday stressors and prevent future relationship problems, especially early in life; promoting social connectedness to increase a sense of belonging and access to informational, tangible, emotional, and social support; and identifying and better supporting persons at risk (e.g., military veterans, persons with physical/mental health conditions) (12). Other strategies include creating protective environments (e.g., reducing access to lethal means among persons at risk for suicide, creating organizational and workplace policies to promote help-seeking, easing transitions into and out of work for persons with mental health conditions and other life challenges), strengthening access and delivery of

care, supporting family and friends after a suicide, and assuring the media follow safe reporting recommendations (12). Some states, such as Colorado, are planning to implement such a comprehensive approach to suicide prevention (10).

The findings in this report are subject to at least three limitations. First, in the state-level analysis, rankings for four states (Maryland, Massachusetts, Rhode Island, and Utah) might have been affected by large proportions of injury deaths of undetermined intent (potentially biasing reported suicide rates downward) or decreased percentages of such deaths over time (potentially biasing estimated rate trends upward). Second, NVDRS is not yet nationally representative; the 27 states included represent 49.6% of the population (<https://factfinder.census.gov/faces/tableservices/jsf/pages/productview.xhtml>). Finally, abstractors of NVDRS data are limited to information contained in investigative reports. Therefore, the extent of informant knowledge can affect data completeness and accuracy. Studies that include more in-depth interviews with next-of-kin often identify greater attributions to mental disorders (13); however, many methodological variations across studies exist (14). It is likely that some persons without known mental health conditions in the current study were experiencing mental health challenges that were unknown, and

## References

## Summary

## What is already known about this topic?

In 2016, nearly 45,000 persons died by suicide in the United States. Mental health conditions can contribute to suicide.

## What is added by this report?

During 1999–2016, suicide rates increased in nearly every state, including >30% increases in 25 states. 2015 data from 27 states indicate 54% of suicide decedents were not known to have mental health conditions. Other contributors included relationship, substance use, health, and job or financial problems, among others.

## What are the implications for public health practice?

A comprehensive approach using proven prevention strategies, such as those in CDC's Technical Package for Suicide Prevention, can help reach the national goal of reducing the annual suicide rate 20% by 2025.

hence underreported by key informants. Nonetheless, the high prevalence of diverse contributing circumstances among those with and without known mental health conditions suggests the importance of addressing the broad range of factors that contribute to suicide.

Suicide is a growing public health problem. Effective approaches to prevent the many suicide risk factors are available. States and communities can use data from NVDRS and resources such as CDC's Preventing Suicide: a Technical Package of Policy, Programs, and Practices (12) to better understand suicide in their populations, prioritize evidence-based comprehensive suicide prevention, and save lives.

## **Vital Signs: Trends in State Suicide Rates — United States, 1999–2016 and Circumstances Contributing to Suicide — 27 States, 2015**

Deborah M. Stone, ScD<sup>1</sup>; Thomas R. Simon PhD<sup>1</sup>; Katherine A. Fowler, PhD<sup>1</sup>; Scott R. Kegler, PhD<sup>2</sup>; Keming Yuan, MS<sup>1</sup>; Kristin M. Holland, PhD<sup>1</sup>; Asha Z. Ivey-Stephenson, PhD<sup>1</sup>; Alex E. Crosby, MD<sup>1</sup>

**Background:** Suicide rates in the United States have risen nearly 30% since 1999, and mental health problems are just one factor contributing to suicide. Examining state-level trends in, and the multiple circumstances contributing to, suicide can inform comprehensive state suicide prevention planning.

**Methods:** Trends in age-adjusted suicide rates among persons aged  $\geq 10$  years, by state and sex, across six consecutive three-year periods (1999–2016), were assessed using data from the National Vital Statistics System for 50 states and the District of Columbia (DC). Data from the National Violent Death Reporting System, covering 27 states in 2015, were used to examine contributing circumstances among decedents with and without known mental health problems.

**Results:** During 1999–2016, suicide rates increased significantly in 44 states, with 25 states experiencing increases of more than 30%. Rates increased significantly among males and females in 34 and 43 states, respectively. In 2015, more than half (54%) of decedents in 27 states did not have a known mental health problem. Among persons with circumstance information, several circumstances were significantly more likely among those without a known mental health problems than among decedents with mental health problems, including relationship problems/loss (45.1% vs 39.6%), life stressors (54.2% vs 49.7%), and recent/impending crises (32.9% vs 26.0%), but these circumstances were common across groups.

**Conclusions:** Suicide rates increased significantly across most states during 1999–2016. Various circumstances contributed to suicides among persons with and without known mental health problems.

**Implications for Public Health Practice:** States can use a comprehensive evidence-based public health approach to prevent suicide risk before it occurs, identify and support persons at risk, prevent reattempts, and help friends/family after a suicide occurs.

## INTRODUCTION

### BACKGROUND AND PURPOSE

In 2016, nearly 45,000 suicides (15.6/100,000 population [age-adjusted]) occurred in the United States, among persons aged  $\geq 10$  years (1). Between 1999 and 2015, suicide rates increased among both sexes, all racial/ethnic groups, and all urbanization levels (2,3). Suicide is the 10<sup>th</sup> leading cause of death and is one of just three leading causes that are increasing (1,4).

Additionally, rates of emergency department visits for nonfatal self-harm, a key risk factor for suicide, increased 42% between 2001 and 2015 (1). Together, suicides and self-harm injuries cost the nation more than \$69 billion in direct medical and work loss costs (1).

The *National Strategy for Suicide Prevention (NSSP)* (5) calls for a public health approach to suicide prevention with efforts spanning multiple levels (i.e., individual, family/relationship, community, and societal). Such a comprehensive approach underscores that suicide is rarely caused by any single factor, but rather, is determined by multiple factors. Despite the NSSP guidance, suicide prevention largely focuses on identifying suicidal persons, providing treatment for mental health problems and preventing reattempts (6). In addition to mental health problems and prior attempts, other circumstances contributing to suicide include social and economic

problems, access to lethal means (e.g., substances, firearms) among persons at risk, and poor coping and problem-solving skills (5). Expanded awareness of these additional circumstances contributing to suicide risk and action to address them can help reach the nation's goal of reducing suicide rates 20% by 2025 (7). To assist states in achieving this goal, CDC analyzed state-specific trends in suicide rates, assessed the multiple contributing factors to suicide, and presents options for multi-level comprehensive suicide prevention based on the best available evidence.

## **METHODS**

Suicide rates were analyzed for persons aged  $\geq 10$  years only, as determining suicidal intent in younger children can be difficult (8). Age-specific suicide counts were tabulated based on National Vital Statistics System coded death certificate records (*International Classification of Diseases 10<sup>th</sup> Revision*, underlying-cause-of death codes X60–X84, Y87.0, U03). Age-specific population estimates were obtained from U.S. Census Bureau/National Center for Health Statistics bridged-race population data releases.

National and state-level suicide rate estimates were calculated for six consecutive three-year aggregate periods spanning 1999–2016 (1999–2001, 2002–2004; 2005–2007; 2008–2010; 2011–2013; and 2014–2016). Rate estimates were age-adjusted to the U.S. year 2000 standard population and expressed per 100,000 persons per year. Age-adjusted suicide rate trends were modeled using the same three-year data aggregates, employing weighted least squares regression with inverse-variance weighting. Modeled rate trends are reported in terms of average annual percentage changes (AAPCs).

Characteristics and circumstances of persons aged  $\geq 10$  years who died by suicide, with and without known mental health problems, were compared in the 27 states with complete data

participating in CDC's National Violent Death Reporting System (NVDRS) in 2015. NVDRS defines mental health problems as disorders and syndromes listed in the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (9), with the exception of alcohol and other substance use disorders, which are captured separately in NVDRS. NVDRS aggregates data from three primary data sources: death certificates, coroner/medical examiner reports (including toxicology), and law enforcement reports. Decedents with and without known mental health problems were compared using Chi-square tests. Logistic regression analyses estimated adjusted odds ratios with 95% confidence intervals (CI), controlling for age group, sex, and race/ethnicity.

## **RESULTS**

The most recent overall suicide rates (representing 2014–2016) varied four-fold, from 6.9 (DC) to 29.2 (Montana) per 100,000 persons per year (available online). Across the study period, rates increased in all states except Nevada (which had a consistently high rate throughout), with absolute increases ranging from +0.8 per 100,000 (Delaware) to +8.1 (Wyoming). Percentage increases in rates ranged from +5.9% (Delaware) to +57.6% (North Dakota), with increases of more than 30% observed in 25 states (available online; Figure 1).

Modeled suicide rate trends indicated significant increases in 44 states, among males (34 states) and females (43 states), as well as for the United States overall (available online). Nationally, the model-estimated AAPC for the overall suicide rate was +1.5%. By sex, estimated national rate trends further indicated significant increases for males (AAPC +1.1%) and females (AAPC +2.6%) (available online).

Suicide decedents without known mental health problems (N = 11,039) were compared with those with known mental health problems (N = 9,407) in 27 states. Whereas all decedents were predominately male (76.8%) (Table 1) and non-Hispanic white (83.6%), those without known

mental health problems, relative to those with mental health problems, were more likely male (83.6% versus 68.8%; odds ratio (OR) = 2.3, 95% CI = 2.2–2.5) and racial/ethnic minorities (OR range: 1.2–2.0). Suicide decedents without known mental health problems also had significantly higher odds of perpetrating homicide-suicide (adjusted odds ratio (aOR) = 2.9, 95% CI = 2.2–3.8). Among adult decedents  $\geq 18$  years, 20.1% of those without known mental health problems and 15.3% of those with mental health problems had ever served, or were currently serving, in the U.S. military.

Whereas firearms were the most common method of suicide overall (48.5%) and for decedents with and without mental health problems, decedents without known mental health problems were more likely to die by firearm (55.3% versus 40.6%) and less likely to die by hanging/strangulation/suffocation (26.9% versus 31.3%) or poisoning (10.4% versus 19.8%) than were those with known mental health problems. These differences remained significant in the adjusted models.

Decedents without known mental health problems were less likely to receive toxicology testing. Among those with toxicology results, decedents without known mental health problems were less likely to test positive for any substance overall (aOR = 0.8, 95% CI = 0.7–0.8), including opioids (aOR = 0.90 95% CI = 0.81–0.99), but were more likely to test positive for alcohol (aOR = 1.2, 95% CI = 1.1–1.3).

Information on circumstances surrounding suicide were available for all decedents with mental health problems (N = 9,407) and approximately 85% of those without known mental health problems (N = 9,357) (Table 2). Persons without known mental health problems were less likely to have any substance use disorders (aOR = 0.7, 95% CI = 0.7–0.8). Whereas two thirds of

decedents with known mental health problems had a history of mental health or substance use treatment (67.2%), just over half (54.0%) were in current treatment.

Decedents without known mental health problems had a significantly higher likelihood of any relationship problem/loss (45.1%) than did those with known mental health problems (39.6%), specifically intimate partner problems (30.2% versus 24.1%), arguments/conflicts (17.5% versus 13.6%), and recently perpetrating interpersonal violence (3.0% versus 1.4%). Decedents without known mental health problems were also more likely than those with known mental health problems to have experienced any life stressors (54.2% versus 49.7%) such as criminal-legal problems (10.7% versus 6.2%) or eviction/loss of home (4.3% versus 3.4%) and were more likely to have had a crisis a current or acute event thought to contribute to the suicide, within the preceding or impending, two weeks (32.9% versus 26.0%). All of these differences remained significant in the adjusted models. Among all persons with recent crises, intimate partner problems were the most common types and did not differ by group. Similarly, physical health problems and job/financial problems were commonly experienced among both persons without mental health problems (23.2% and 15.6%, respectively) and those with mental health problems (21.4% and 16.8%, respectively).

Decedents without known mental health problems had significantly lower odds of recent release from any institution (aOR = 0.5, 95% CI = 0.4–0.5), but those who were recently released (5.1%), were significantly more likely to have been released from a correctional facility (25.7% versus 8.7%), hospital (43.7% versus 33.0%), or other facility (e.g., alcohol/substance treatment) (aOR = 2.5 95% CI = 1.8–3.3), than those with a known mental health problems. Among decedents with known mental health problems who were recently released from an institution (10.2%), 46.7% of were released from psychiatric facilities.

Decedents without known mental health problems were significantly less likely to have a history of suicidal ideation (23.0%) or prior suicide attempts (10.3%) compared with those with known mental health problems (40.8% and 29.4%, respectively). Suicide intent was disclosed by 22.4% and 24.5% of persons without and with known mental health problems, respectively.

### **Conclusions and Comments**

During 1999–2016, suicide rates increased significantly in 44 states, and 25 states experienced increases of more than 30%. Rates increased significantly among males in 34 states, and females, in 43 states. This finding is consistent with prior research showing a decreasing gender gap in male-female suicide rates during 1999–2014 (3). Additional research into the specific causes of these trends is necessary. Fortunately, data from the 27 states participating in NVDRS provides important insight into circumstances surrounding suicide and can help states identify prevention priorities.

Suicidologists regularly state that suicide is not caused by a single factor (5); however, suicide prevention is often oriented toward downstream identification of suicidal persons, treatment of mental health problems and prevention of reattempts. This study found that more than half of suicide decedents in NVDRS did not have a known mental health problems, indicating that additional focus on non-mental health factors, further upstream, is essential to a public health approach (10). This group suffered more from relationship problems and other life stressors such as criminal-legal matters, eviction/loss of home, and recent or impending crises.

Similarly, persons with mental health problems often experienced relationship problems and other life stressors such as job/financial and/or physical health problems. These findings point to the need to both help persons manage the conditions associated with mental health problems in the first place, and to support persons with known mental health problems to decrease their risk

of poor outcomes (11). Two thirds of this group had a history of any mental health and/or substance use treatment, with over half in treatment when they died. This suggests the need for additional safety supports, including broader implementation of affordable and effective treatment modalities such as doctor-patient collaborative care models and proven cognitive-behavioral therapies. Additionally, increased access to behavioral health providers in underserved areas is needed, as is expansion of health care systems that integrate physical and behavioral health, with a priority on suicide prevention and patient safety, especially through care transitions (12).

Comprehensive statewide suicide prevention activities are needed to address the full range of factors contributing to suicide. Prevention strategies include strengthening economic supports (e.g., housing stabilization policies, household financial support); teaching coping and problem-solving skills to manage everyday stressors and prevent future relationship problems, especially early in life; promoting social connectedness to increase a sense of belonging and access to informational, tangible, emotional, and social support; and identifying and better supporting persons at risk (e.g., military veterans, persons with physical/mental health problems) (12). Other strategies include creating protective environments (e.g., reducing access to lethal means among persons at risk, creating organizational and workplace policies to promote help-seeking, easing transitions into and out of work for persons with mental health problems and other life challenges), supporting family and friends after a suicide, and assuring safe reporting by the media in order to prevent suicide contagion (12). Some states, such as Colorado, are planning to implement such a comprehensive approach to suicide prevention (10).

The findings in this report are subject to at least three limitations. In the state-level analysis, rankings for four states (Maryland, Massachusetts, Rhode Island, and Utah) might have been

affected by large proportions of injury deaths of undetermined intent (potentially biasing reported suicide rates downward), or decreased percentages of such deaths over time (potentially biasing estimated rate trends upward). Second, NVDRS is not yet nationally representative; the 27 states included represent 49.6% of the population

(<https://factfinder.census.gov/faces/tableservices/jsf/pages/productview.xhtml>). Finally, abstractors of NVDRS data are limited to information contained in investigative reports.

Therefore, the extent of informant knowledge can affect data completeness and accuracy. Studies including more in-depth interviews with next-of-kin often identify greater attributions to mental disorders (13); however, many methodological variations across studies exist (14). It is likely that some persons without known mental health problems in the current study were experiencing mental health challenges that were unknown, and hence underreported by key informants.

Nonetheless, the high prevalence of diverse contributing circumstances among those with and without known mental health problems suggests the importance of addressing the broad range of factors that contribute to suicide.

Suicide is a growing public health problem. Effective approaches to prevent the many suicide risk factors are available. States and communities can use data from NVDRS and resources such as CDC's *Preventing Suicide: a Technical Package of Policies, Programs, and Practices* (12) to better understand their suicide problem, prioritize evidence-based comprehensive suicide prevention, and save lives.

### **Summary Box (word count 100/100)**

#### **What is already known on the topic?**

In 2016, nearly 45,000 lives were lost to suicide in the U.S.

#### **What is added by this report?**

Between 1999-2016, suicide rates increased in nearly every state. Twenty-five states saw rate increases >30%. Mental health problems often contribute to suicide, however, 2015 data from the National Violent Death Reporting System (27 states) indicate that 54% of suicide decedents

were not known to have such problems. Other contributors included relationship, substance use, health, and job/financial problems.

**What are the implications for public health practice?**

A comprehensive approach using proven prevention strategies, such as those in CDC's Technical Package for Suicide Prevention, can help reach the national goal of reducing suicide rates 20% by 2025.

## **Vital Signs: Trends in State Suicide Rates — United States, 1999–2016 and Circumstances Contributing to Suicide — 27 States, 2015**

Deborah M. Stone, ScD<sup>1</sup>; Thomas R. Simon PhD<sup>1</sup>; Katherine A. Fowler, PhD<sup>1</sup>; Scott R. Kegler, PhD<sup>2</sup>; Keming Yuan, MS<sup>1</sup>; Kristin M. Holland, PhD<sup>1</sup>; Asha Z. Ivey-Stephenson, PhD<sup>1</sup>; Alex E. Crosby, MD<sup>1</sup>

**Background:** Suicide rates in the United States have risen nearly 30% since 1999, and mental health problems are just one factor contributing to suicide. Examining state-level trends in, and the multiple circumstances contributing to, suicide can inform comprehensive state suicide prevention planning.

**Methods:** Trends in age-adjusted suicide rates among persons aged  $\geq 10$  years, by state and sex, across six consecutive three-year periods (1999–2016), were assessed using data from the National Vital Statistics System for 50 states and the District of Columbia (DC). Data from the National Violent Death Reporting System, covering 27 states in 2015, were used to examine contributing circumstances among decedents with and without known mental health problems.

**Results:** During 1999–2016, suicide rates increased significantly in 44 states, with 25 states experiencing increases of more than 30%. Rates increased significantly among males and females in 34 and 43 states, respectively. In 2015, more than half (54%) of decedents in 27 states did not have a known mental health problem. Among decedents with circumstance information available, several circumstances were significantly more likely among those without a known mental health problems than among those with mental health problems, including relationship problems/loss (45.1% versus 39.6%), life stressors (54.2% versus 49.7%), and recent/impending crises (32.9% versus 26.0%), but these circumstances were common across groups.

**Conclusions:** Suicide rates increased significantly across most states during 1999–2016. Various circumstances contributed to suicides among persons with and without known mental health problems.

**Implications for Public Health Practice:** States can use a comprehensive evidence-based public health approach to prevent suicide risk before it occurs, identify and support persons at risk, prevent reattempts, and help friends and family in the aftermath of a suicide.

## INTRODUCTION

### BACKGROUND AND PURPOSE

In 2016, nearly 45,000 suicides (15.6/100,000 population [age-adjusted]) occurred in the United States among persons aged  $\geq 10$  years (1). Between 1999 and 2015, suicide rates increased among both sexes, all racial/ethnic groups, and all urbanization levels (2,3). Suicide is the 10<sup>th</sup> leading cause of death and is one of just three leading causes that are increasing (1,4).

Additionally, rates of emergency department visits for nonfatal self-harm, a key risk factor for suicide, increased 42% between 2001 and 2015 (1). Together, suicides and self-harm injuries cost the nation more than \$69 billion in direct medical and work loss costs (1).

The *National Strategy for Suicide Prevention (NSSP)* (5) calls for a public health approach to suicide prevention with efforts spanning multiple levels (i.e., individual, family/relationship, community, and societal). Such a comprehensive approach underscores that suicide is rarely caused by any single factor, but rather, is determined by multiple factors. Despite the NSSP guidance, suicide prevention largely focuses on identifying suicidal persons, providing treatment for mental health problems, and preventing reattempts (6). In addition to mental health problems and prior attempts, other circumstances contributing to suicide include social and economic

problems, access to lethal means (e.g., substances, firearms) among persons at risk, and poor coping and problem-solving skills (5). Expanded awareness of these additional circumstances contributing to suicide risk and action to address them can help reach the nation's goal of reducing suicide rates by 20% by 2025 (7). To assist states in achieving this goal, CDC analyzed state-specific trends in suicide rates and assessed the multiple contributing factors to suicide; this report presents options for multi-level comprehensive suicide prevention based on the best available evidence.

## **METHODS**

Suicide rates were analyzed for persons aged  $\geq 10$  years only, as determining suicidal intent in younger children can be difficult (8). Age-specific suicide counts were tabulated based on National Vital Statistics System coded death certificate records (*International Classification of Diseases 10<sup>th</sup> Revision*, underlying-cause-of death codes X60–X84, Y87.0, U03). Age-specific population estimates were obtained from U.S. Census Bureau/National Center for Health Statistics bridged-race population data releases.

National and state-level suicide rate estimates were calculated for six consecutive three-year aggregate periods spanning 1999–2016 (1999–2001, 2002–2004; 2005–2007; 2008–2010; 2011–2013; and 2014–2016). Rate estimates were age-adjusted to the U.S. year 2000 standard population and expressed per 100,000 persons per year. Age-adjusted suicide rate trends were modeled using the same three-year data aggregates, employing weighted least squares regression with inverse-variance weighting. Modeled rate trends are reported in terms of average annual percentage changes (AAPCs).

Characteristics of persons aged  $\geq 10$  years who died by suicide, with and without known mental health problems, and the circumstances surrounding the suicides were compared in the 27 states

with complete data participating in CDC's National Violent Death Reporting System (NVDRS) in 2015. NVDRS defines mental health problems as disorders and syndromes listed in the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (9), with the exception of alcohol and other substance use disorders, which are captured separately in NVDRS. NVDRS aggregates data from three primary data sources: death certificates, coroner/medical examiner reports (including toxicology), and law enforcement reports. Decedents with and without known mental health problems were compared using Chi-square tests. Logistic regression analyses estimated adjusted odds ratios with 95% confidence intervals (CI), controlling for age group, sex, and race/ethnicity.

## **RESULTS**

The most recent overall suicide rates (representing 2014–2016) varied four-fold, from 6.9 (DC) to 29.2 (Montana) per 100,000 persons per year (Supplementary Table). Across the study period, rates increased in all states except Nevada (where the rate was consistently high throughout the study period), with absolute increases ranging from +0.8 per 100,000 (Delaware) to +8.1 (Wyoming). Percentage increases in rates ranged from +5.9% (Delaware) to +57.6% (North Dakota), with increases of more than 30% observed in 25 states (Supplementary Table) (Figure 1).

Modeled suicide rate trends indicated significant increases in 44 states, among males (34 states) and females (43 states), as well as for the United States overall (Supplementary Table).

Nationally, the model-estimated AAPC for the overall suicide rate was +1.5%. By sex, estimated national rate trends further indicated significant increases for males (AAPC +1.1%) and females (AAPC +2.6%) (Supplementary Table).

Suicide decedents without known mental health problems (N = 11,039) were compared with those with known mental health problems (N = 9,407) in 27 states. Whereas all decedents were predominately male (76.8%) (Table 1) and non-Hispanic white (83.6%), those without known mental health problems, relative to those with mental health problems, were more likely male (83.6% versus 68.8%; odds ratio (OR) = 2.3, 95% CI = 2.2–2.5) and racial/ethnic minorities (OR range: 1.2–2.0). Suicide decedents without known mental health problems also had significantly higher odds of perpetrating homicide-suicide (adjusted odds ratio (aOR) = 2.9, 95% CI = 2.2–3.8). Among adult decedents aged  $\geq 18$  years, 20.1% of those without known mental health problems and 15.3% of those with mental health problems had ever served, or were currently serving, in the U.S. military.

Whereas firearms were the most common method of suicide overall (48.5%) and among decedents with and without mental health problems, decedents without known mental health problems, relative to those with known mental health problems, were more likely to die by firearm (55.3% versus 40.6%) and less likely to die by hanging/strangulation/suffocation (26.9% versus 31.3%) or poisoning (10.4% versus 19.8%). These differences remained significant in the adjusted models.

Decedents without known mental health problems were less likely to receive toxicology testing. Among those with toxicology results, decedents without known mental health problems were less likely to test positive for any substance overall (aOR = 0.8, 95% CI = 0.7–0.8), including opioids (aOR = 0.90 95% CI = 0.81–0.99), but were more likely to test positive for alcohol (aOR = 1.2, 95% CI = 1.1–1.3).

Information on circumstances surrounding suicide were available for all decedents with mental health problems (N = 9,407) and approximately 85% of those without known mental health

problems (N = 9,357) in 27 states (Table 2). Persons without known mental health problems were less likely to have any substance use disorders (aOR = 0.7, 95% CI = 0.7–0.8) than were persons with known mental health problems. Whereas two thirds of decedents with known mental health problems had a history of mental health or substance use treatment (67.2%), just over half (54.0%) were in current treatment.

Decedents without known mental health problems had a significantly higher likelihood of any relationship problem/loss (45.1%) than did those with known mental health problems (39.6%), specifically intimate partner problems (30.2% versus 24.1%), arguments/conflicts (17.5% versus 13.6%), and recently perpetrating interpersonal violence (3.0% versus 1.4%). Decedents without known mental health problems were also more likely than were those with known mental health problems to have experienced any life stressors (54.2% versus 49.7%) such as criminal-legal problems (10.7% versus 6.2%) or eviction/loss of home (4.3% versus 3.4%) and were more likely to have had a recent or impending (within the preceding or upcoming 2 weeks, respectively) crisis (a current or acute event thought to contribute to the suicide) (32.9% versus 26.0%). All of these differences remained significant in the adjusted models. Among all persons with recent crises, intimate partner problems were the most common types and did not differ by group. Similarly, physical health problems and job/financial problems were commonly experienced among both persons without mental health problems (23.2% and 15.6%, respectively) and those with mental health problems (21.4% and 16.8%, respectively).

Decedents without known mental health problems had significantly lower odds of recent release from any institution (aOR = 0.5, 95% CI = 0.4–0.5), but those who were recently released (5.1%), were significantly more likely to have been released from a correctional facility (25.7% versus 8.7%), hospital (43.7% versus 33.0%), or other facility (e.g., alcohol/substance treatment)

(aOR = 2.5 95% CI = 1.8–3.3), than were those with a known mental health problem. Among decedents with known mental health problems who were recently released from an institution (10.2%), 46.7% of were released from psychiatric facilities.

Decedents without known mental health problems were significantly less likely to have a history of suicidal ideation (23.0%) or prior suicide attempts (10.3%) compared with those with known mental health problems (40.8% and 29.4%, respectively). Suicide intent was disclosed by 22.4% and 24.5% of persons without and with known mental health problems, respectively.

### **Conclusions and Comments**

During 1999–2016, suicide rates increased significantly in 44 states, and 25 states experienced increases of more than 30%. Rates increased significantly among males in 34 states, and females, in 43 states. This finding is consistent with prior research showing a decreasing gender gap in male-female suicide rates during 1999–2014 (3). Additional research into the specific causes of these trends is necessary. Data from the 27 states participating in NVDRS provides important insight into circumstances surrounding suicide and can help states identify prevention priorities.

Suicidologists regularly state that suicide is not caused by a single factor (5); however, suicide prevention is often oriented toward downstream identification of suicidal persons, treatment of mental health problems and prevention of reattempts. This study found that more than half of suicide decedents in NVDRS did not have a known mental health problems, indicating that additional focus on non-mental health factors, further upstream, is essential to a public health approach (10). This group suffered more from relationship problems and other life stressors such as criminal-legal matters, eviction/loss of home, and recent or impending crises.

Similarly, persons with mental health problems often experienced relationship problems and other life stressors such as job/financial and/or physical health problems. These findings point to the need to both help persons manage the conditions associated with mental health problems in the first place, and to support persons with known mental health problems to decrease their risk of poor outcomes (11). Two thirds of this group had a history of any mental health and/or substance use treatment, with over half in treatment when they died. This suggests the need for additional safety supports, including broader implementation of affordable and effective treatment modalities such as doctor-patient collaborative care models and proven cognitive-behavioral therapies. Additionally, increased access to behavioral health providers in underserved areas is needed, as is expansion of health care systems that integrate physical and behavioral health, with a priority on suicide prevention and patient safety, especially through care transitions (12).

Comprehensive statewide suicide prevention activities are needed to address the full range of factors contributing to suicide. Prevention strategies include strengthening economic supports (e.g., housing stabilization policies, household financial support); teaching coping and problem-solving skills to manage everyday stressors and prevent future relationship problems, especially early in life; promoting social connectedness to increase a sense of belonging and access to informational, tangible, emotional, and social support; and identifying and better supporting persons at risk (e.g., military veterans, persons with physical/mental health problems) (12). Other strategies include creating protective environments (e.g., reducing access to lethal means among persons at risk, creating organizational and workplace policies to promote help-seeking, easing transitions into and out of work for persons with mental health problems and other life challenges), supporting family and friends after a suicide, and assuring safe reporting by the

media in order to prevent suicide contagion (12). Some states, such as Colorado, are planning to implement such a comprehensive approach to suicide prevention (10).

The findings in this report are subject to at least three limitations. In the state-level analysis, rankings for four states (Maryland, Massachusetts, Rhode Island, and Utah) might have been affected by large proportions of injury deaths of undetermined intent (potentially biasing reported suicide rates downward), or decreased percentages of such deaths over time (potentially biasing estimated rate trends upward). Second, NVDRS is not yet nationally representative; the 27 states included represent 49.6% of the population

(<https://factfinder.census.gov/faces/tableservices/jsf/pages/productview.xhtml>). Finally, abstractors of NVDRS data are limited to information contained in investigative reports.

Therefore, the extent of informant knowledge can affect data completeness and accuracy. Studies including more in-depth interviews with next-of-kin often identify greater attributions to mental disorders (13); however, many methodological variations across studies exist (14). It is likely that some persons without known mental health problems in the current study were experiencing mental health challenges that were unknown, and hence underreported by key informants.

Nonetheless, the high prevalence of diverse contributing circumstances among those with and without known mental health problems suggests the importance of addressing the broad range of factors that contribute to suicide.

Suicide is a growing public health problem. Effective approaches to prevent the many suicide risk factors are available. States and communities can use data from NVDRS and resources such as CDC's *Preventing Suicide: a Technical Package of Policies, Programs, and Practices* (12) to better understand their suicide problem, prioritize evidence-based comprehensive suicide prevention, and save lives.

## **Summary**

### **What is already known about this topic?**

In 2016, nearly 45,000 lives were lost to suicide in the United States.

**What is added by this report?**

During 1999–2016, suicide rates increased in nearly every state, including >30% increases in 25 states. Mental health problems often contribute to suicide; however, 2015 data from the National Violent Death Reporting System (27 states) indicate that 54% of suicide decedents were not known to have such problems. Other contributors included relationship, substance use, health, and job/financial problems.

**What are the implications for public health practice?**

A comprehensive approach using proven prevention strategies, such as those in CDC's Technical Package for Suicide Prevention, can help reach the national goal of reducing suicide rates 20% by 2025.

### **Vital Signs: Trends in State Suicide Rates — United States, 1999–2016 and Circumstances Contributing to Suicide — 27 States, 2015**

Deborah M. Stone, ScD<sup>1</sup>; Thomas R. Simon PhD<sup>1</sup>; Katherine A. Fowler, PhD<sup>1</sup>; Scott R. Kegler, PhD<sup>2</sup>; Keming Yuan, MS<sup>1</sup>; Kristin M. Holland, PhD<sup>1</sup>; Asha Z. Ivey-Stephenson, PhD<sup>1</sup>; Alex E. Crosby, MD<sup>1</sup>

**Background:** Suicide rates in the United States have risen nearly 30% since 1999, and mental health problems are just one factor contributing to suicide. Examining state-level trends in, and the multiple circumstances contributing to, suicide can inform comprehensive state suicide prevention planning.

**Methods:** Trends in age-adjusted suicide rates among persons aged  $\geq 10$  years, by state and sex, across six consecutive three-year periods (1999–2016), were assessed using data from the National Vital Statistics System for 50 states and the District of Columbia (DC). Data from the National Violent Death Reporting System, covering 27 states in 2015, were used to examine contributing circumstances among decedents with and without known mental health problems.

**Results:** During 1999–2016, suicide rates increased significantly in 44 states, with 25 states experiencing increases of more than 30%. Rates increased significantly among males and females in 34 and 43 states, respectively. In 2015, more than half (54%) of decedents in 27 states did not have a known mental health problem. Among persons with circumstance information, several circumstances were significantly more likely among those without a known mental health problems than among decedents with mental health problems, including relationship problems/loss (45.1% vs 39.6%), life stressors (54.2% vs 49.7%), and recent/impending crises (32.9% vs 26.0%), but these circumstances were common across groups.

**Conclusions:** Suicide rates increased significantly across most states during 1999–2016. Various circumstances contributed to suicides among persons with and without known mental health problems.

**Implications for Public Health Practice:** States can use a comprehensive evidence-based public health approach to prevent suicide risk before it occurs, identify and support persons at risk, prevent reattempts, and help friends/family after a suicide occurs.

## INTRODUCTION

### BACKGROUND AND PURPOSE

In 2016, nearly 45,000 suicides (15.6/100,000 population [age-adjusted]) occurred in the United States, among persons aged  $\geq 10$  years (1). Between 1999 and 2015, suicide rates increased among both sexes, all racial/ethnic groups, and all urbanization levels (2,3). Suicide is the 10<sup>th</sup> leading cause of death and is one of just three leading causes that are increasing (1,4).

Additionally, rates of emergency department visits for nonfatal self-harm, a key risk factor for suicide, increased nearly 45% between 2001 and 2015 (1). Together, suicides and self-harm injuries cost the nation more than \$69 billion in direct medical and work loss costs (1).

The *National Strategy for Suicide Prevention (NSSP)* (5) calls for a public health approach to suicide prevention with efforts spanning multiple levels (i.e., individual, family/relationship, community, and societal). Such a comprehensive approach underscores that suicide is rarely caused by any single factor, but rather, is determined by multiple factors. Despite the NSSP guidance, suicide prevention largely focuses on identifying suicidal persons, providing treatment for mental health problems and preventing reattempts (6). In addition to mental health problems and prior attempts, other circumstances contributing to suicide include social and economic

problems, access to lethal means (e.g., substances, firearms) among persons at risk, and poor coping and problem-solving skills (5). Expanded awareness of these additional circumstances contributing to suicide risk and action to address them can help reach the nation's goal of reducing suicide rates 20% by 2025 (7). To assist states in achieving this goal, CDC analyzed state-specific trends in suicide rates, assessed the multiple contributing factors to suicide, and presents options for multi-level comprehensive suicide prevention based on the best available evidence.

## **METHODS**

Suicide rates were analyzed for persons aged  $\geq 10$  years only, as determining suicidal intent in younger children can be difficult (8). Age-specific suicide counts were tabulated based on National Vital Statistics System coded death certificate records (*International Classification of Diseases 10<sup>th</sup> Revision*, underlying-cause-of death codes X60–X84, Y87.0, U03). Age-specific population estimates were obtained from U.S. Census Bureau/National Center for Health Statistics bridged-race population data releases.

National and state-level suicide rate estimates were calculated for six consecutive three-year aggregate periods spanning 1999–2016 (1999–2001, 2002–2004; 2005–2007; 2008–2010; 2011–2013; and 2014–2016). Rate estimates were age-adjusted to the U.S. year 2000 standard population and expressed per 100,000 persons per year. Age-adjusted suicide rate trends were modeled using the same three-year data aggregates, employing weighted least squares regression with inverse-variance weighting. Modeled rate trends are reported in terms of average annual percentage changes (AAPCs).

Characteristics and circumstances of persons aged  $\geq 10$  years who died by suicide, with and without known mental health problems, were compared in the 27 states with complete data

participating in CDC's National Violent Death Reporting System (NVDRS) in 2015. NVDRS defines mental health problems as disorders and syndromes listed in the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (9), with the exception of alcohol and other substance use disorders, which are captured separately in NVDRS. NVDRS aggregates data from three primary data sources: death certificates, coroner/medical examiner reports (including toxicology), and law enforcement reports. Decedents with and without known mental health problems were compared using Chi-square tests. Logistic regression analyses estimated adjusted odds ratios with 95% confidence intervals (CI), controlling for age group, sex, and race/ethnicity.

## **RESULTS**

The most recent overall suicide rates (representing 2014–2016) varied four-fold, from 6.9 (DC) to 29.2 (Montana) per 100,000 persons per year (Table 1). Across the study period, rates increased in all states except Nevada (which had a consistently high rate throughout), with absolute increases ranging from +0.8 per 100,000 (Delaware) to +8.1 (Wyoming). Percentage increases in rates ranged from +5.9% (Delaware) to +57.6% (North Dakota), with increases of more than 30% observed in 25 states (Table 1) (Figure).

Modeled suicide rate trends indicated significant increases in 44 states (Table 1), among males (34 states) and females (43 states; Supplemental Table 1), as well as for the United States overall (Table 1). Nationally, the model-estimated AAPC for the overall suicide rate was +1.5%. By sex, estimated national rate trends further indicated significant increases for males (AAPC +1.1%) and females (AAPC +2.6%) (Supplemental Table 1).

Suicide decedents without known mental health problems (N = 11,039) were compared with those with known mental health problems (N = 9,407) in 27 states. Whereas all decedents were predominately male (76.8%) (Table 2) and non-Hispanic white (83.6%), those without known

mental health problems, relative to those with mental health problems, were more likely male (83.6% versus 68.8%; odds ratio (OR) = 2.3, 95% CI = 2.2–2.5) and racial/ethnic minorities (OR range: 1.2–2.0). Suicide decedents without known mental health problems also had significantly higher odds of perpetrating homicide-suicide (adjusted odds ratio (aOR) = 2.9, 95% CI = 2.2–3.8). Among adult decedents  $\geq 18$  years, 20.1% of those without known mental health problems and 15.3% of those with mental health problems had ever served, or were currently serving, in the U.S. military.

Whereas firearms were the most common method of suicide overall (48.5%) and for decedents with and without mental health problems, decedents without known mental health problems were more likely to die by firearm (55.3% versus 40.6%) and less likely to die by hanging/strangulation/suffocation (26.9% versus 31.3%) or poisoning (10.4% versus 19.8%) than were those with known mental health problems. These differences remained significant in the adjusted models.

Decedents without known mental health problems were less likely to receive toxicology testing. Among those with toxicology results, decedents without known mental health problems were less likely to test positive for any substance overall (aOR = 0.8, 95% CI = 0.7–0.8), including opioids (aOR = 0.90 95% CI = 0.81–0.99), but were more likely to test positive for alcohol (aOR = 1.2, 95% CI = 1.1–1.3).

Information on circumstances surrounding suicide were available for all decedents with mental health problems (N = 9,407) and approximately 85% of those without known mental health problems (N = 9,357) (Table 3). Persons without known mental health problems were less likely to have any substance use disorders (aOR = 0.7, 95% CI = 0.7–0.8). Whereas two thirds of

decedents with known mental health problems had a history of mental health or substance use treatment (67.2%), just over half (54.0%) were in current treatment.

Decedents without known mental health problems had a significantly higher likelihood of any relationship problem/loss (45.1%) than did those with known mental health problems (39.6%), specifically intimate partner problems (30.2% versus 24.1%), arguments/conflicts (17.5% versus 13.6%), and recently perpetrating interpersonal violence (3.0% versus 1.4%). Decedents without known mental health problems were also more likely than those with known mental health problems to have experienced any life stressors (54.2% versus 49.7%) such as criminal-legal problems (10.7% versus 6.2%) or eviction/loss of home (4.3% versus 3.4%) and were more likely to have had a crisis a current or acute event thought to contribute to the suicide, within the preceding or impending, two weeks (32.9% versus 26.0%). All of these differences remained significant in the adjusted models. Among all persons with recent crises, intimate partner problems were the most common types and did not differ by group. Similarly, physical health problems and job/financial problems were commonly experienced among both persons without mental health problems (23.2% and 15.6%, respectively) and those with mental health problems (21.4% and 16.8%, respectively).

Decedents without known mental health problems had significantly lower odds of recent release from any institution (aOR = 0.5, 95% CI = 0.4–0.5), but those who were recently released (5.1%), were significantly more likely to have been released from a correctional facility (25.7% versus 8.7%), hospital (43.7% versus 33.0%), or other facility (e.g., alcohol/substance treatment) (aOR = 2.5 95% CI = 1.8–3.3), than those with a known mental health problems. Among decedents with known mental health problems who were recently released from an institution (10.2%), 46.7% of were released from psychiatric facilities.

Decedents without known mental health problems were significantly less likely to have a history of suicidal ideation (23.0%) or prior suicide attempts (10.3%) compared with those with known mental health problems (40.8% and 29.4%, respectively). Suicide intent was disclosed by 22.4% and 24.5% of persons without and with known mental health problems, respectively.

### **Conclusions and Comments**

During 1999–2016, suicide rates increased significantly in 44 states, and 25 states experienced increases of more than 30%. Rates increased significantly among males in 34 states, and females, in 43 states. This finding is consistent with prior research showing a decreasing gender gap in male-female suicide rates during 1999–2014 (3). Additional research into the specific causes of these trends is necessary. Fortunately, data from the 27 states participating in NVDRS provides important insight into circumstances surrounding suicide and can help states identify prevention priorities.

Suicidologists regularly state that suicide is not caused by a single factor (5); however, suicide prevention is often oriented toward downstream identification of suicidal persons, treatment of mental health problems and prevention of reattempts. This study found that more than half of suicide decedents in NVDRS did not have a known mental health problems, indicating that additional focus on non-mental health factors, further upstream, is essential to a public health approach (10). This group suffered more from relationship problems and other life stressors such as criminal-legal matters, eviction/loss of home, and recent or impending crises.

Similarly, persons with mental health problems often experienced relationship problems and other life stressors such as job/financial and/or physical health problems. These findings point to the need to both help persons manage the conditions associated with mental health problems in the first place, and to support persons with known mental health problems to decrease their risk

of poor outcomes (11). Two thirds of this group had a history of any mental health and/or substance use treatment, with over half in treatment when they died. This suggests the need for additional safety supports, including broader implementation of affordable and effective treatment modalities such as doctor-patient collaborative care models and proven cognitive-behavioral therapies. Additionally, increased access to behavioral health providers in underserved areas is needed, as is expansion of health care systems that integrate physical and behavioral health, with a priority on suicide prevention and patient safety, especially through care transitions (12).

Comprehensive statewide suicide prevention activities are needed to address the full range of factors contributing to suicide. Prevention strategies include strengthening economic supports (e.g., housing stabilization policies, household financial support); teaching coping and problem-solving skills to manage everyday stressors and prevent future relationship problems, especially early in life; promoting social connectedness to increase a sense of belonging and access to informational, tangible, emotional, and social support; and identifying and better supporting persons at risk (e.g., military veterans, persons with physical/mental health problems) (12). Other strategies include creating protective environments (e.g., reducing access to lethal means among persons at risk, creating organizational and workplace policies to promote help-seeking, easing transitions into and out of work for persons with mental health problems and other life challenges), supporting family and friends after a suicide, and assuring safe reporting by the media in order to prevent suicide contagion (12). Some states, such as Colorado, are planning to implement such a comprehensive approach to suicide prevention (10).

The findings in this report are subject to at least three limitations. In the state-level analysis, rankings for four states (Maryland, Massachusetts, Rhode Island, and Utah) might have been

affected by large proportions of injury deaths of undetermined intent (potentially biasing reported suicide rates downward), or decreased percentages of such deaths over time (potentially biasing estimated rate trends upward). Second, NVDRS is not yet nationally representative; the 27 states included represent 49.6% of the population

(<https://factfinder.census.gov/faces/tableservices/jsf/pages/productview.xhtml>). Finally, abstractors of NVDRS data are limited to information contained in investigative reports.

Therefore, the extent of informant knowledge can affect data completeness and accuracy. Studies including more in-depth interviews with next-of-kin often identify greater attributions to mental disorders (13); however, many methodological variations across studies exist (14). It is likely that some persons without known mental health problems in the current study were experiencing mental health challenges that were unknown, and hence underreported by key informants.

Nonetheless, the high prevalence of diverse contributing circumstances among those with and without known mental health problems suggests the importance of addressing the broad range of factors that contribute to suicide.

Suicide is a growing public health problem. Effective approaches to prevent the many suicide risk factors are available. States and communities can use data from NVDRS and resources such as CDC's *Preventing Suicide: a Technical Package of Policies, Programs, and Practices* (12) to better understand their suicide problem, prioritize evidence-based comprehensive suicide prevention, and save lives.

### **Summary Box (word count 100/100)**

#### **What is already known on the topic?**

In 2016, nearly 45,000 lives were lost to suicide in the U.S.

#### **What is added by this report?**

Between 1999-2016, suicide rates increased in nearly every state. Twenty-five states saw rate increases >30%. Mental health problems often contribute to suicide, however, 2015 data from the National Violent Death Reporting System (27 states) indicate that 54% of suicide decedents

were not known to have such problems. Other contributors included relationship, substance use, health, and job/financial problems.

**What are the implications for public health practice?**

A comprehensive approach using proven prevention strategies, such as those in CDC's Technical Package for Suicide Prevention, can help reach the national goal of reducing suicide rates 20% by 2025.

## Trends in Suicide Rates among Persons ≥ 10 Years of Age, by State and Sex, 1999 – 2016

State	Sex	Age-Adjusted Annual Rate per 100,000 Persons (Change from Prior Period) *						Modeled AAPC †	Current State Rank §	Overall Rate Change (State Rank) ¶	Overall Percent Change (State Rank) **
		1999 – 2001	2002 – 2004	2005 – 2007	2008 – 2010	2011 – 2013	2014 – 2016				
U.S.	Both	12.3 (n/a)	12.7 (+ 0.4)	12.9 (+ 0.2)	13.8 (+ 0.9)	14.5 (+ 0.8)	15.4 (+ 0.9)	+ 1.5 % (p<.01)	n/a	+ 3.1 (n/a)	+ 25.4 % (n/a)
	Male	20.9 (n/a)	21.2 (+ 0.4)	21.3 (+ 0.0)	22.5 (+1.3)	23.5 (+ 1.0)	24.5 (+ 1.0)	+ 1.1 % (p<.01)			
	Female	4.7 (n/a)	5.0 (+ 0.3)	5.3 (+ 0.2)	5.7 (+ 0.4)	6.2 (+ 0.5)	6.9 (+ 0.7)	+ 2.6 % (p<.01)			
AL	Both	14.3 (n/a)	13.4 (- 0.9)	14.1 (+ 0.6)	15.6 (+ 1.6)	16.4 (+ 0.7)	17.5 (+ 1.1)	+ 1.6 % (p<.05)	25	+ 3.1 (31)	+ 21.9 % (33)
	Male	25.1 (n/a)	23.4 (- 1.7)	24.4 (+ 1.0)	26.4 (+ 2.0)	27.6 (+ 1.1)	29.1 (+ 1.5)	+ 1.3 % (p<.05)			
	Female	5.1 (n/a)	4.8 (- 0.3)	5.0 (+ 0.2)	6.1 (+ 1.1)	6.4 (+ 0.3)	7.0 (+ 0.7)	+ 2.6 % (p<.01)			
AK	Both	21.0 (n/a)	24.8 (+ 3.8)	24.2 (- 0.6)	26.0 (+ 1.7)	25.4 (- 0.5)	28.8 (+ 3.4)	+ 1.7 % (p<.05)	2	+ 7.8 ( 4)	+ 37.4 % (13)
	Male	33.2 (n/a)	38.1 (+ 4.9)	38.9 (+ 0.8)	40.1 (+ 1.2)	40.1 (- 0.1)	42.9 (+ 2.8)	+ 1.4 % (p<.01)			
	Female	8.6 (n/a)	11.4 (+ 2.9)	9.8 (- 1.6)	11.1 (+ 1.2)	9.9 (- 1.2)	13.2 (+ 3.4)	+ 1.7 % n/s

\* Rates are age-adjusted to the U.S. year 2000 standard.

† Model-estimated average annual percentage change (AAPC) based on all reporting periods; p-value indicates statistical significance of trend; n/s indicates trend not significant.

§ Current state rank (50 states and the District of Columbia) is for the reporting period 2014 – 2016. Ranks are from highest rate (1) to lowest rate (51). Differences between ranks do not necessarily imply a statistically significant difference.

¶ Overall rate change is between the first (1999 – 2001) and last (2014 – 2016) reporting periods. Ranks are from largest increase (1) to largest decrease (51). Differences between ranks do not necessarily imply a statistically significant difference.

\*\* Overall percent change in rates is between the first (1999 – 2001) and last (2014 – 2016) reporting periods. Ranks are from largest percentage increase (1) to largest percentage decrease (51). Differences between ranks do not necessarily imply a statistically significant difference.

†† Rate based on < 20 suicides.

§§ Percentage of injury deaths for which intent was not determined exceeded 20% for both the first and last periods and might have contributed to lower reported rates.

¶¶ Percentage of injury deaths for which intent was not determined declined notably between the first and last periods and might have contributed to the reported rate increase.

\* Rates are age-adjusted to the U.S. year 2000 standard.

† Model-estimated average annual percentage change (AAPC) based on all reporting periods; p-value indicates statistical significance of trend; n/s indicates trend not significant.

§ Current state rank (50 states and the District of Columbia) is for the reporting period 2014 – 2016. Ranks are from highest rate (1) to lowest rate (51). Differences between ranks do not necessarily imply a statistically significant difference.

¶ Overall rate change is between the first (1999 – 2001) and last (2014 – 2016) reporting periods. Ranks are from largest increase (1) to largest decrease (51). Differences between ranks do not necessarily imply a statistically significant difference.

\*\* Overall percent change in rates is between the first and last periods. Ranks are from largest percentage increase (1) to largest percentage decrease (51). Differences between ranks do not necessarily imply a statistically significant difference.

†† Rate based on < 20 suicides.

§§ Percentage of injury deaths for which intent was not determined exceeded 20% for both the first and last periods and might have contributed to lower reported rates.

¶¶ Percentage of injury deaths for which intent was not determined declined notably between the first and last periods and might have contributed to the reported rate increase.

\* Rates are age-adjusted to the U.S. year 2000 standard.

† Model-estimated average annual percentage change (AAPC) based on all reporting periods; p-value indicates statistical significance of trend; n/s indicates trend not significant.

§ Current state rank (50 states and the District of Columbia) is for the reporting period 2014 – 2016. Ranks are from highest rate (1) to lowest rate (51). Differences between ranks do not necessarily imply a statistically significant difference.

¶ Overall rate change is between the first (1999 – 2001) and last (2014 – 2016) reporting periods. Ranks are from largest increase (1) to largest decrease (51). Differences between ranks do not necessarily imply a statistically significant difference.

\*\* Overall percent change in rates is between the first and last periods. Ranks are from largest percentage increase (1) to largest percentage decrease (51). Differences between ranks do not necessarily imply a statistically significant difference.

†† Rate based on < 20 suicides.

§§ Percentage of injury deaths for which intent was not determined exceeded 20% for both the first and last periods and might have contributed to lower reported rates.

¶¶ Percentage of injury deaths for which intent was not determined declined notably between the first and last periods and might have contributed to the reported rate increase.

### Trends in Suicide Rates among Persons ≥ 10 Years of Age, by State and Sex, 1999 – 2016

\* Alaska, Arizona, Colorado, Connecticut, Georgia, Hawaii, Kansas, Kentucky, Maine, Maryland, Massachusetts, Michigan, Minnesota, New Hampshire, New Jersey, New Mexico, New York, North Carolina, Ohio, Oklahoma, Oregon, Rhode Island, South Carolina, Utah, Vermont, Virginia, and Wisconsin.

† Decedent had been identified as having a current diagnosis of mental health problem in coroner/medical examiner or law enforcement reports.

§ Odds ratio reflects the risk among those without known mental health problem relative to those with known MHP.

¶ Logistic regression was used to estimate adjusted odds ratio with 95% CIs after controlling for age, sex, race and ethnicity. Known MHP was used as the reference group.

\*\* Decedents were aged 10 years and older, as per standard in the suicide prevention literature.

†† Denominator is decedents aged 18 years of age and older with reported military service status.

§§ Denominator is decedents who died by poisoning, including overdose.

¶¶ Denominator is decedents with any toxicology tested.

\*\*\* Denominator for each positive group is the number tested for the substance in that group.

<sup>†</sup> Decedent had been identified as having a current diagnosis of mental health problem in coroner/medical examiner or law enforcement reports.

§ Odds ratio reflects the risk among those without known mental health problem relative to those with known MHP.

¶ Logistic regression was used to estimate adjusted odds ratio with 95% CIs after controlling for age, sex, race and ethnicity. Known MHP was used as the reference group.

\*\* Includes decedents with one or more diagnosed current mental health problems, which are not mutually exclusive. Therefore sums of percentages for the diagnosed conditions exceed 100%. Denominator includes the number of decedents with one or more current diagnosed mental health problems.

†† Denominator is decedents aged 18 years of age and older.

§§ Denominator is decedents aged 10-18 years.

¶¶ Denominator of institution subgroup is decedents with recent release from an institution. Recent release from an institution is defined as having occurred within the past month.

\*\*\* Denominator of crisis subgroup is decedents with any crisis within past or upcoming two weeks. Crises depicted here represent the most commonly occurring categories.

\* Rates are age-adjusted to the U.S. year 2000 standard.

† Model-estimated average annual percentage change (AAPC) based on all reporting periods; p-value indicates statistical significance of trend; n/s indicates trend not significant.

§ Current state rank (50 states and the District of Columbia) is for the reporting period 2014 – 2016. Ranks are from highest rate (1) to lowest rate (51). Differences between ranks do not necessarily imply a statistically significant difference.

¶ Overall rate change is between the first (1999 – 2001) and last (2014 – 2016) reporting periods. Ranks are from largest increase (1) to largest decrease (51). Differences between ranks do not necessarily imply a statistically significant difference.

\*\* Overall percent change in rates is between the first (1999 – 2001) and last (2014 – 2016) reporting periods. Ranks are from largest percentage increase (1) to largest percentage decrease (51). Differences between ranks do not necessarily imply a statistically significant difference.

†† Rate based on < 20 suicides.

§§ Percentage of injury deaths for which intent was not determined exceeded 20% for both the first and last periods and might have contributed to lower reported rates.

¶¶ Percentage of injury deaths for which intent was not determined declined notably between the first and last periods and might have contributed to the reported rate increase.

\* Rates are age-adjusted to the U.S. year 2000 standard.

† Model-estimated average annual percentage change (AAPC) based on all reporting periods; p-value indicates statistical significance of trend; n/s indicates trend not significant.

§ Current state rank (50 states and the District of Columbia) is for the reporting period 2014 – 2016. Ranks are from highest rate (1) to lowest rate (51). Differences between ranks do not necessarily imply a statistically significant difference.

¶ Overall rate change is between the first (1999 – 2001) and last (2014 – 2016) reporting periods. Ranks are from largest increase (1) to largest decrease (51). Differences between ranks do not necessarily imply a statistically significant difference.

\*\* Overall percent change in rates is between the first (1999 – 2001) and last (2014 – 2016) reporting periods. Ranks are from largest percentage increase (1) to largest percentage decrease (51). Differences between ranks do not necessarily imply a statistically significant difference.

†† Rate based on < 20 suicides.

§§ Percentage of injury deaths for which intent was not determined exceeded 20% for both the first and last periods and might have contributed to lower reported rates.

¶¶ Percentage of injury deaths for which intent was not determined declined notably between the first and last periods and might have contributed to the reported rate increase.

\* Alaska, Arizona, Colorado, Connecticut, Georgia, Hawaii, Kansas, Kentucky, Maine, Maryland, Massachusetts, Michigan, Minnesota, New Hampshire, New Jersey, New Mexico, New York, North Carolina, Ohio, Oklahoma, Oregon, Rhode Island, South Carolina, Utah, Vermont, Virginia, and Wisconsin.

† Decedent had been identified as having a current diagnosis of mental health problem in coroner/medical examiner or law enforcement reports.

§ Odds ratio reflects the risk among those without known mental health problem relative to those with known MHP.

¶ Logistic regression was used to estimate adjusted odds ratio with 95% CIs after controlling for age, sex, race and ethnicity. Known MHP was used as the reference group.

\*\* Decedents were aged 10 years and older, as per standard in the suicide prevention literature.

†† Denominator is decedents aged 18 years of age and older with reported military service status.

§§ Denominator is decedents who died by poisoning, including overdose.

¶¶ Denominator is decedents with any toxicology tested.

\*\*\* Denominator for each positive group is the number tested for the substance in that group.

<sup>†</sup> Decedent had been identified as having a current diagnosis of mental health problem in coroner/medical examiner or law enforcement reports.

§ Odds ratio reflects the risk among those without known mental health problem relative to those with known MHP.

¶ Logistic regression was used to estimate adjusted odds ratio with 95% CIs after controlling for age, sex, race and ethnicity. Known MHP was used as the reference group.

\*\* Includes decedents with one or more diagnosed current mental health problems, which are not mutually exclusive. Therefore sums of percentages for the diagnosed conditions exceed 100%. Denominator includes the number of decedents with one or more current diagnosed mental health problems.

†† Denominator is decedents aged 18 years of age and older.

§§ Denominator is decedents aged 10-18 years.

¶¶ Denominator of institution subgroup is decedents with recent release from an institution. Recent release from an institution is defined as having occurred within the past month.

\*\*\* Denominator of crisis subgroup is decedents with any crisis within past or upcoming two weeks. Crises depicted here represent the most commonly occurring categories.

\* Rates are age-adjusted to the U.S. year 2000 standard.

† Model-estimated average annual percentage change (AAPC) based on all reporting periods; p-value indicates statistical significance of trend; n/s indicates trend not significant.

§ Current state rank (50 states and the District of Columbia) is for the reporting period 2014 – 2016. Ranks are from highest rate (1) to lowest rate (51). Differences between ranks do not necessarily imply a statistically significant difference.

¶ Overall rate change is between the first (1999 – 2001) and last (2014 – 2016) reporting periods. Ranks are from largest increase (1) to largest decrease (51). Differences between ranks do not necessarily imply a statistically significant difference.

\*\* Overall percent change in rates is between the first (1999 – 2001) and last (2014 – 2016) reporting periods. Ranks are from largest percentage increase (1) to largest percentage decrease (51). Differences between ranks do not necessarily imply a statistically significant difference.

†† Rate based on < 20 suicides.

§§ Percentage of injury deaths for which intent was not determined exceeded 20% for both the first and last periods and might have contributed to lower reported rates.

¶¶ Percentage of injury deaths for which intent was not determined declined notably between the first and last periods and might have contributed to the reported rate increase.

\* Rates are age-adjusted to the U.S. year 2000 standard.

† Model-estimated average annual percentage change (AAPC) based on all reporting periods; p-value indicates statistical significance of trend; n/s indicates trend not significant.

§ Current state rank (50 states and the District of Columbia) is for the reporting period 2014 – 2016. Ranks are from highest rate (1) to lowest rate (51). Differences between ranks do not necessarily imply a statistically significant difference.

¶ Overall rate change is between the first (1999 – 2001) and last (2014 – 2016) reporting periods. Ranks are from largest increase (1) to largest decrease (51). Differences between ranks do not necessarily imply a statistically significant difference.

\*\* Overall percent change in rates is between the first (1999 – 2001) and last (2014 – 2016) reporting periods. Ranks are from largest percentage increase (1) to largest percentage decrease (51). Differences between ranks do not necessarily imply a statistically significant difference.

†† Rate based on < 20 suicides.

§§ Percentage of injury deaths for which intent was not determined exceeded 20% for both the first and last periods and might have contributed to lower reported rates.

¶¶ Percentage of injury deaths for which intent was not determined declined notably between the first and last periods and might have contributed to the reported rate increase.

\* Rates are age-adjusted to the U.S. year 2000 standard.

† Model-estimated average annual percentage change (AAPC) based on all reporting periods; p-value indicates statistical significance of trend; n/s indicates trend not significant.

§ Current state rank (50 states and the District of Columbia) is for the reporting period 2014 – 2016. Ranks are from highest rate (1) to lowest rate (51). Differences between ranks do not necessarily imply a statistically significant difference.

¶ Overall rate change is between the first (1999 – 2001) and last (2014 – 2016) reporting periods. Ranks are from largest increase (1) to largest decrease (51). Differences between ranks do not necessarily imply a statistically significant difference.

\*\* Overall percent change in rates is between the first (1999 – 2001) and last (2014 – 2016) reporting periods. Ranks are from largest percentage increase (1) to largest percentage decrease (51). Differences between ranks do not necessarily imply a statistically significant difference.

†† Rate based on < 20 suicides.

§§ Percentage of injury deaths for which intent was not determined exceeded 20% for both the first and last periods and might have contributed to lower reported rates.

¶¶ Percentage of injury deaths for which intent was not determined declined notably between the first and last periods and might have contributed to the reported rate increase.

\* Alaska, Arizona, Colorado, Connecticut, Georgia, Hawaii, Kansas, Kentucky, Maine, Maryland, Massachusetts, Michigan, Minnesota, New Hampshire, New Jersey, New Mexico, New York, North Carolina, Ohio, Oklahoma, Oregon, Rhode Island, South Carolina, Utah, Vermont, Virginia, and Wisconsin.

† Decedent had been identified as having a current diagnosis of mental health problem in coroner/medical examiner or law enforcement reports.

§ Odds ratio reflects the risk among those without known mental health problem relative to those with known MHP.

¶ Logistic regression was used to estimate adjusted odds ratio with 95% CIs after controlling for age, sex, race and ethnicity. Known MHP was used as the reference group.

\*\* Decedents were aged 10 years and older, as per standard in the suicide prevention literature.

†† Denominator is decedents aged 18 years of age and older with reported military service status.

§§ Denominator is decedents who died by poisoning, including overdose.

¶¶ Denominator is decedents with any toxicology tested.

\*\*\* Denominator for each positive group is the number tested for the substance in that group.

\*Alaska, Arizona, Colorado, Connecticut, Georgia, Hawaii, Kansas, Kentucky, Maine, Maryland, Massachusetts, Michigan, Minnesota, New Hampshire, New Jersey, New Mexico, New York, North Carolina, Ohio, Oklahoma, Oregon, Rhode Island, South Carolina, Utah, Vermont, Virginia, and Wisconsin.

<sup>†</sup> Decedent had been identified as having a current diagnosis of mental health problem in coroner/medical examiner or law enforcement reports.

§ Odds ratio reflects the risk among those without known mental health problem relative to those with known MHP.

¶ Logistic regression was used to estimate adjusted odds ratio with 95% CIs after controlling for age, sex, race and ethnicity. Known MHP was used as the reference group.

\*\* Includes decedents with one or more diagnosed current mental health problems, which are not mutually exclusive. Therefore sums of percentages for the diagnosed conditions exceed 100%. Denominator includes the number of decedents with one or more current diagnosed mental health problems.

†† Denominator is decedents aged 18 years of age and older.

§§ Denominator is decedents aged 10-18 years.

¶¶ Denominator of institution subgroup is decedents with recent release from an institution. Recent release from an institution is defined as having occurred within the past month.

\*\*\* Denominator of crisis subgroup is decedents with any crisis within past or upcoming two weeks. Crises depicted here represent the most commonly occurring categories.

\*Alaska, Arizona, Colorado, Connecticut, Georgia, Hawaii, Kansas, Kentucky, Maine, Maryland, Massachusetts, Michigan, Minnesota, New Hampshire, New Jersey, New Mexico, New York, North Carolina, Ohio, Oklahoma, Oregon, Rhode Island, South Carolina, Utah, Vermont, Virginia, and Wisconsin.

<sup>†</sup> Decedent had been identified as having a current diagnosis of mental health problem in coroner/medical examiner or law enforcement reports.

<sup>§</sup> Odds ratio reflects the risk among those without known mental health problem relative to those with known MHP.

<sup>†</sup> Logistic regression was used to estimate adjusted odds ratio with 95% CIs after controlling for age, sex, race and ethnicity. Known MHP was used as the reference group.

<sup>\*\*</sup> Includes decedents with one or more diagnosed current mental health problems, which are not mutually exclusive. Therefore sums of percentages for the diagnosed conditions exceed 100%. Denominator includes the number of decedents with one or more current diagnosed mental health problems.

<sup>††</sup> Denominator is decedents aged 18 years of age and older.

§§ Denominator is decedents aged 10-18 years.

¶ Denominator of institution subgroup is decedents with recent release from an institution. Recent release from an institution is defined as having occurred within the past month.

\*\*\* Denominator of crisis subgroup is decedents with any crisis within past or upcoming two weeks. Crises depicted here represent the most commonly occurring categories.

\* Alaska, Arizona, Colorado, Connecticut, Georgia, Hawaii, Kansas, Kentucky, Maine, Maryland, Massachusetts, Michigan, Minnesota, New Hampshire, New Jersey,

<sup>†</sup> Decedent had been identified as having a current diagnosis of mental health problem in coroner/medical examiner or law enforcement reports.

<sup>§</sup> Odds ratio reflects the risk among those without known mental health problem relative to those with known MHP.

<sup>†</sup> Logistic regression was used to estimate adjusted odds ratio with 95% CIs after controlling for age, sex, race and ethnicity. Known MHP was used as the reference group.

<sup>\*\*</sup> Decedents were aged 10 years and older, as per standard in the suicide prevention literature.

<sup>††</sup> Denominator is decedents aged 18 years of age and older with reported military service status.

<sup>§§</sup> Denominator is decedents who died by poisoning, including overdose.

<sup>¶¶</sup> Denominator is decedents with any toxicology tested.

<sup>\*\*\*</sup> Denominator for each positive group is the number tested for the substance in that group.

<sup>†</sup> Decedent had been identified as having a current diagnosis of mental health problem in coroner/medical examiner or law enforcement reports.

<sup>§</sup> Odds ratio reflects the risk among those without known mental health problem relative to those with known MHP.

<sup>†</sup> Logistic regression was used to estimate adjusted odds ratio with 95% CIs after controlling for age, sex, race and ethnicity. Known MHP was used as the reference group.

<sup>\*\*</sup> Includes decedents with one or more diagnosed current mental health problems, which are not mutually exclusive. Therefore sums of percentages for the diagnosed conditions exceed 100%. Denominator includes the number of decedents with one or more current diagnosed mental health problems.

<sup>††</sup> Denominator is decedents aged 18 years of age and older.

§§ Denominator is decedents aged 10-18 years.

¶ Denominator of institution subgroup is decedents with recent release from an institution. Recent release from an institution is defined as having occurred within the past month.

\*\*\* Denominator of crisis subgroup is decedents with any crisis within past or upcoming two weeks. Crises depicted here represent the most commonly occurring categories.

## Overview

This technical package represents a select group of strategies based on the best available evidence to help communities and states sharpen their focus on prevention activities with the greatest potential to prevent suicide. Broadly, the strategies represented include those with a focus on preventing suicide from happening in the first place as well as approaches to lessen the immediate and long-term effects of suicidal behavior for individuals, families, communities, and society. Specifically, the strategies include strengthening economic supports; strengthening access to mental health care; establishing protective environments; promoting connectedness to protect against suicide; teaching coping and problem-solving skills; identifying and supporting people at-risk; and intervening to lessen harms and prevent future risk.

This package supports the National Strategy for Suicide prevention, Goal 1, “Integrate and coordinate suicide prevention activities across multiple sectors and settings.” (p.29) It also supports the National Action Alliance for Suicide Prevention’s priority (2016) “To create and disseminate a framework for comprehensive community-based suicide prevention.”

Commitment, cooperation, and leadership from numerous sectors, including public health, education, justice, health care, social services, business/labor, and government can bring about the successful implementation of this package.

### What is a Technical Package?

A technical package is a compilation of a core set of strategies to achieve and sustain substantial reductions in a specific risk factor or outcome (Frieden, 2014). Technical packages help communities and states prioritize prevention activities based on the best available evidence. This technical package has three components. The first component is the **strategy** or the preventive direction or actions to achieve the goal of preventing suicide. The second component is the **approach**. The approach includes the specific ways to advance the strategy. This can be accomplished through *programs, policies, and practices*. The approaches included come primarily from studies based in the United States. The **evidence** for each of the approaches in preventing suicide or its associated risk factors is included as the third component. This package is intended as a resource to guide and inform prevention decision-making in communities and states.

### Preventing Suicide is a Priority

Suicide, as defined by the CDC, is part of a broader class of behavior called *self-directed violence*. Self-directed violence refers to behavior directed at oneself that deliberately results in injury or the *potential* for injury (Crosby, Ortega, & Melanson, 2011). Self-directed violence may be *suicidal* or *non-suicidal* in nature. For the purposes of this document, we refer only to behavior where suicide is intended.

- **Suicide** is a death caused by self-directed injurious behavior with any intent to die as a result of the behavior.
- **Suicide attempt** is defined as a *non-fatal* self-directed and potentially injurious behavior with any intent to die as a result of the behavior. A suicide attempt may or may not result in injury.

### **Suicide is highly prevalent.**

Suicidal behavior presents a major challenge to public health in the United States and worldwide. It contributes to premature death, morbidity, lost productivity, and health care costs (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014). In 2014 in the U.S., the most recent death data available, suicide was responsible for 42,773 deaths, which is approximately one suicide every 12 minutes (Centers for Disease Control and Prevention, 2005). In 2014, suicide ranked as the tenth leading cause of death and has been among the top twelve leading causes of death since 1975 in the U.S (Centers for Disease Control and Prevention, 2005). Overall suicide rates have increased from 1999 to 2014 (24% increase) (Curtin, Warner, & Hedegaard, 2016). Suicide is a problem throughout the life span; it is the second leading cause of death among those aged 10–19 years, also second among persons in their 20s and 30s; it is the fourth leading cause among persons in their 40s and seventh among persons in their 50s (Centers for Disease Control and Prevention, 2005).

Suicides reflect only a portion of the number of persons affected by suicidal thoughts and behaviors (Crosby, Han, Ortega, Parks, & Gfroerer, 2011). Substantially more persons are hospitalized as a result of nonfatal suicidal behaviors than are fatally injured, and an even greater number are either treated in ambulatory settings or not treated at all (Crosby, Han, et al., 2011). For example, during 2014, among adults aged  $\geq 18$  years, for every one suicide there were 9 adults treated in hospital emergency departments for self-inflicted injuries, 27 who reported making a suicide attempt, and over 227 who reported seriously considering suicide (Ferdon et al., In press). Suicides, attempts, and ideation take an immense emotional, physical, and economic toll on individuals, families and communities. By one estimate, for every death by suicide six people are directly impacted (i.e. survivors). Based on this figure it is estimated that there are over 13 million survivors in the U.S. and unfortunately, survivorship itself is a risk factor for suicide (Crosby & Sacks, 2002).

### **Suicide is associated with several risk and protective factors.**

Suicide, like other human behaviors, is complex with no single determining cause. It occurs in response to multiple biological, psychological, interpersonal, environmental and societal influences that interact with one another and act cumulatively to increase one's vulnerability to think about or engage in suicidal behaviors. The social-ecological model is a useful framework for viewing and understanding suicidal risk factors that have been identified in the literature (Dahlber & Krug, 2002):

Risk Factors for Suicide (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014)

- ❑ **Individual:** History of depression and other mental illnesses, alcohol and drug abuse, previous suicide attempt, previous victimization, acute and chronic stressors (e.g. financial problems), genetic and biological determinants, hopelessness
- ❑ **Relationship:** High conflict or violent relationships, sense of isolation and lack of social support, family history of suicide, financial and work stress
- ❑ **Community:** Inadequate community connectedness, barriers to health care-- lack of access to providers or medications
- ❑ **Societal:** Availability of lethal means of suicide, unsafe media portrayals of suicide, stigma associated with help-seeking

An individual having or experiencing one or a number of risk factors does not always result in suicide; for example, the vast majority of individuals who are depressed do not die by suicide. It is also important to note that the risk factors described above is not an exhaustive list. These and many other risk factors exist and can be arranged differently or contribute to multiple areas within the social-ecological model. Furthermore, the relevance of each risk factor can vary by age, race, gender, sexual orientation, residential geography, and socio-cultural and economic status (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014)

Protective factors, or those influences that guard against the risk for suicide, can also be found across the different levels of the social-ecological model. Protective factors identified in the literature include: effective coping and problem solving skills, moral objections to suicide, strong and supportive relationships with partners, peers, and family, connectedness to school, community and other social institutions and the availability of physical and mental health care (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014). These protective factors can either counter a specific risk factor or guard against a number of risks associated with suicide.

**Suicide is connected to other forms of violence.**

Suicide is connected to other forms of violence in a number of ways. First, suicide and other forms of violence often share some of the same root causes. They can all take place under one roof, or in a given community and can happen at the same time or at different stages of life (Butchart, Phinney, Check, & Villaveces, 2004; Klevens, Simon, & Chen, 2012). For example, in neighborhoods where there is low cohesion, or where residents don't support and trust each other, people are at higher risk for suicide (Desai, Dausey, & Rosenheck, 2005) as well as perpetration of child maltreatment (Coulton, Crampton, Irwin, Spilsbury, & Korbin, 2007; Freisthler, Merritt, & LaScala, 2006), teen dating violence (Capaldi, Knoble, Shortt, & Kim, 2012), intimate partner violence (Pinchevsky & Wright, 2012), and youth violence (Sampson, Morenoff, & Gannon-Rowley, 2002). Lack of economic opportunities and unemployment are associated with suicide (Luo, Florence, Quispe-Agnoli, Ouyang, & Crosby, 2011; Reeves et al., 2012), as well as perpetration of child maltreatment (D. Runyan, Wattam, Ikeda, Hassan, & Ramiro, 2002), intimate partner violence (Heise & Garcia-Moreno, 2002; Pinchevsky & Wright, 2012), sexual violence (Centers for Disease Control and Prevention, 2016c) and youth violence (Wilson, 2011). Also, while most people who are victims of violence do not act violently or die by suicide, people who experience or are exposed to suicide are at a higher risk for both being a victim of other forms of violence and for inflicting harm on others. For example, children who experience physical abuse or neglect early in their lives are at greater risk for suicide (Briere, Madni, & Godbout, 2015), and also at greater risk for committing violence against peers (particularly for boys) (Logan, Leeb, & Barker, 2009), bullying (Duke, Pettingell, McMorris, & Borowsky, 2010), teen dating violence (Duke et al., 2010), and committing child abuse, elder abuse, intimate partner violence (American Psychological Association, 1996), and sexual violence (Jewkes, 2012), later in life. There are also a number of protective factors that pose an opportunity to protect individuals and communities from suicide and other forms of violence, and buffer the effects of shared risk factors. For example, connectedness increases people's and communities' resilience to suicide and other forms of violence, including connectedness to one's community (Basile, Hamburger, Swahn, & Choi, 2013; Borowsky, Hogan, & Ireland, 1997; Centers for Disease Control and Prevention, 2016b; Coulton et al., 2007; Kleiman, Riskind, Schaefer, & Weingarden, 2012; Pinchevsky & Wright, 2012; Widome, Sieving, Harpin, & Hearst, 2008), school (Basile, Espelage, Rivers, McMahon, & Simon, 2009; Capaldi et al., 2012; Carter, McGee, Taylor, & Williams, 2007; DeGue et al., 2013; Hong, Kral, Espelage, & Allen-Meares, 2012; Losel & Farrington, 2012), family (Capaldi et al., 2012; Centers for Disease Control and Prevention, 2016a; Elgar, Craig, Boyce, Morgan, & Vella-Zarb, 2009; Maimon, Browning, & Brooks-Gunn, 2010; Resnick, Ireland, & Borowsky, 2004), caring adults (Capaldi et al., 2012; Losel & Farrington, 2012; Maimon et al., 2010), and pro-social peers (Capaldi et al., 2012; Losel & Farrington, 2012).

### **The health and economic consequences of suicide are substantial.**

Suicide has far-reaching consequences for individuals, families, and communities. Research indicates that the health consequences of violence, even self-directed, are much more comprehensive than merely injury and death. Suicide attempt survivors may suffer from health consequences ranging from anger, guilt, and mental health problems to traumatic brain injury and physical impairment, depending

on the means and severity of the attempt (Chapman & Dixon-Gordon, 2007). Further, for each person who dies by suicide, it is estimated that there are an estimated 18 people (called survivors) (Cerel, 2015) who experience a major life disruption, such as complicated grief (Mitchell, Kim, Prigerson, & Mortimer-Stephens, 2004), stigma, depression, anxiety, post-traumatic stress disorder, and increased risk of suicidal ideation and suicide (Cvinar, 2005; Runeson & Asberg, 2003).

The economic toll of suicide is immense as well. The total lifetime costs associated with nonfatal injuries and deaths caused by self-directed violence in 2013 were approximately \$93.5 billion after adjusting for under-reporting of suicide (Shepard, Gurewich, Lwin, Reed, & Silverman, 2016). The overwhelming burden of these costs results from lost productivity over the life course, with the average cost per suicide being over \$1.3 million (Shepard et al., 2016).

### **Suicide can be prevented.**

Despite the myths surrounding suicide, like most public health problems, suicide is preventable. And while progress will continue to be made into the future, evidence for numerous programs, practices, and policies currently exists, and many programs are ready to be implemented now. Just as suicide is not caused by a single factor, research suggests that suicide will not be prevented by any single intervention taking place in any single setting (Silverman & Maris, 1995; U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012). Rather, suicide prevention is best achieved by a focus across the individual-, relationship-, family-, community, and societal-levels and across all sectors, private and public (e.g., business, public health, physical and behavioral healthcare, justice, education, labor)(National Action Alliance for Suicide Prevention, 2014; World Health Organization, 2014). According to CDC Director, Tom Frieden, successful public health programs also require political commitment, funding, communication, and performance monitoring (Frieden, 2014).

### **Assessing the Evidence**

This technical package includes programs, practices, and policies with evidence of impact on suicide or risk or protective factors for suicide. To be considered for inclusion in the technical package, the program, practice, or policy selected had to meet at least one of these criteria: a) meta-analyses or systematic reviews showing impact on suicide; b) evidence from at least one rigorous (e.g., randomized controlled trial [RCT] or quasi-experimental design) evaluation study that found significant preventive effects on suicide; c) meta-analyses or systematic reviews showing impact on risk or protective factors for suicide, or d) evidence from at least one rigorous (e.g., RCT or quasi-experimental design) evaluation study that found significant impacts on risk or protective factors for suicide. Finally, consideration was also given to the likelihood of achieving beneficial effects on multiple forms of violence; no evidence of harmful effects on specific outcomes or with particular subgroups; and feasibility of implementation in a U.S. context if the program, policy, or practice has been evaluated in another country.

Within this technical package, some approaches do not yet have research evidence demonstrating impact on rates of suicide but instead are supported by evidence indicating impacts on risk or protective factors for suicide (e.g., help-seeking, stigma reduction, depression, connectedness). In terms of the strength of the evidence, programs that have demonstrated effects on suicidal behavior (e.g., reductions in deaths, attempts) provide a higher-level of evidence, but the evidence base is not that strong in all areas. For instance, there has been less evaluation of community engagement and family programs on suicidal behavior. Thus, approaches in this package that have effects on risk or protective factors reflect the developmental nature of the evidence base and the use of the best available evidence at a given time.

It is also important to note that there is often significant heterogeneity among the programs, policies, or practices that fall within one approach or strategy area in terms of the nature and quality of the available evidence. Not all programs, policies, or practices that utilize the same approach (e.g., gatekeeper training) are equally effective, and even those that are effective may not work across all populations. Tailoring programs and more evaluation may be necessary to address different population groups. The examples provided are not intended to be a comprehensive list of evidence-based programs, policies, or practices for each approach, but rather illustrate models that have been shown to impact suicide or have beneficial effects on risk or protective factors for suicide. In practice, the effectiveness of the programs, policies and practices identified in this package will be strongly dependent on the quality of their implementation and the communities in which they are implemented. Implementation guidance to assist practitioners, organizations and communities will be developed separately.

### Context and Cross-Cutting Themes

The strategies and approaches that have been included in this technical package represent different levels of the social ecology, with efforts intended to impact the community and societal levels, as well individual and relationship levels. The strategies and approaches are intended to work in combination and reinforce each other to prevent suicide (see box below). The strategies are arranged in order such that those strategies hypothesized to have the greatest potential for broad public health impact on suicide are included first, followed by those that might impact more select populations (e.g., persons who have already made a suicide attempt).

Preventing Suicide	
Strategy	Approach
Strengthen economic supports	<ul style="list-style-type: none"> <li>Strengthen financial security</li> <li>Housing stabilization policies</li> </ul>
Strengthen access to mental health care	<ul style="list-style-type: none"> <li>Coverage of mental health conditions in health</li> </ul>

	insurance policies
Establish protective environments	<ul style="list-style-type: none"> <li>• Means restriction</li> <li>• Organizational policies and culture</li> <li>• Community-based policies to reduce excessive alcohol use</li> </ul>
Promote connectedness to protect against suicide	<ul style="list-style-type: none"> <li>• Peer norm approaches</li> <li>• Community engagement activities</li> </ul>
Teach coping and problem-solving skills	<ul style="list-style-type: none"> <li>• Social-emotional learning</li> <li>• Parenting skill and family relationship approaches</li> </ul>
Identify and support people at risk	<ul style="list-style-type: none"> <li>• Gatekeeper training</li> <li>• Screening combined with care management</li> <li>• Crisis intervention</li> </ul>
Intervene to lessen harms and prevent future risk	<ul style="list-style-type: none"> <li>• Treatment for people at-risk of suicide</li> <li>• Treatment to prevent re-attempts</li> <li>• Postvention</li> <li>• Safe messaging following a suicide</li> </ul>

The example programs, policies, and practices have been implemented within particular contexts. The social and cultural context of communities is critically important to take into account when selecting strategies and approaches. Practitioners in the field may be in the best position to assess the needs and strengths of their communities and work with community members to make decisions about the combination of approaches included here that are best suited to their context.

[Add text for other issues to potentially cover in this section. You may want to take a look at the other packages in this regard]

This package includes strategies where public health agencies are well positioned to bring leadership and resources to implementation efforts. It also includes strategies where public health can serve as an important collaborator (e.g., strategies addressing community and societal level risks), but where leadership and commitment from other sectors such as business/labor or health care is critical to implement a particular policy or program (e.g., workplace policies; screening combined with care management). The role of various sectors in the implementation of a strategy or approach in preventing suicide is described further in the section on *Sector Involvement*.

In the sections that follow, the strategies and approaches with the best available evidence for preventing suicide are described.

## Strengthen Economic Supports

### Rationale

Research consistently links difficult economic conditions, unemployment, and home foreclosures to increased rates of suicide (Fowler, Gladden, Vagi, Barnes, & Frazier, 2015; Luo et al., 2011).

Strengthening financial security may prevent suicide by reducing stress and negative economic outcomes associated with unemployment or underemployment, such as home foreclosures and evictions, which are also associated with suicide risk. Thus, policies that have the potential to improve the socioeconomic conditions of individuals experiencing economic hardship may reduce the risk of suicide.

### Approaches

Economic and housing supports for individuals and families can be strengthened by improving policies through enhancing financial security and stabilizing housing assistance options during times of economic need.

- **Strengthen household financial security.** Research indicates that economic crises are related to suicide rates. Findings from the U.S. show that suicide rates increase during economic recessions marked by high unemployment rates, job losses, and economic instability and decrease during economic expansions and periods marked by low unemployment rates, particularly for working-age individuals 25 to 64 years old (Fowler et al., 2015; Luo et al., 2011). Policies that support financial security during difficult economic times have been shown to mitigate the risk of economic crises on suicide rates.
  - *Unemployment benefit programs* provide income protection during periods of unemployment in an effort to prevent or lessen the economic hardship for those experiencing job loss and enduring unemployment. These benefits may buffer suicide risk during economic crises by increasing financial security and reducing emotional distress among the unemployed. Greater financial assistance through unemployment benefits has been shown to mitigate the risk of unemployment on suicide.
- **Housing stabilization policies** that aim to strengthen housing stability and security may help to buffer the impact of foreclosures and evictions on suicide, as recent research has drawn an association between housing instability and suicidal behavior. Programs that provide affordable housing and other options for homebuyers such as loan modification programs may be used in conjunction with move-out planning and financial counseling services to minimize the impact of foreclosures and evictions on suicide.

- *The National Neighborhood Stabilization Program* was designed to help neighborhoods suffering from high rates of foreclosure and abandonment by slowing the deterioration of the neighborhoods and providing affordable housing options for low, moderate, and middle-income homebuyers. This program also offers financial assistance to eligible individuals for the purchase of a new home.

### Potential Outcomes

- Reduced suicide rates
- Lower foreclosure rates
- Lower eviction rates

### Evidence

To date, much research in this area has focused on the association between economic depressions or recessions and suicide rates; however, some studies have demonstrated the impact of public programs on these associations.

- **Strengthen household financial security.** An examination of variations in U.S. *unemployment benefit programs* across states demonstrated that the impact of unemployment on suicide was offset in those states that provided unemployment benefits greater than the national average across all states (Cylus, Glymour, & Avendano, 2014). Another U.S. study of the link between unemployment and suicide risk using monthly data on suicides, length of unemployment, and job losses found that duration, as opposed to merely the loss of a job, predicted suicide risk (Classen & Dunn, 2012). Together, these results suggest that to help prevent suicide, not only should state unemployment benefit programs be **generous** in their financial allocations, but also in their duration.
- **Housing stabilization policies.** Although the *National Neighborhood Stabilization Program* has not been rigorously evaluated for its impact on suicide outcomes, it addresses foreclosure and eviction, which are risk factors for suicide. A longitudinal analysis of annual data on suicides and foreclosures demonstrated that as the proportion of foreclosed properties increased in U.S. states, so did the state suicide rate, particularly among working-aged adults (Houle & Light, 2014). Another study of data from 16 U.S. states participating in the National Violent Death Reporting System found that suicides precipitated by home foreclosures and evictions increased more than 100% from 2005 (before the housing crisis began) to 2010 (after it had peaked; Fowler et al. (2015)). Most of these suicides occurred prior to the actual loss of the decedent's home. These findings suggest that integrating suicide prevention resources, messaging, and referrals into financial, foreclosure, and move-out planning and counseling services may help to prevent suicide.

**Comment [A]:** Tom had a concern about this term so we've tried to explain it above. Hopefully it's a bit clearer. The interpretation from the study isn't the easiest.

## Strengthen Access to Mental Health Care

### Rationale

Mental illness is a risk factor for suicide. Studies suggest that up to 90% of people who die by suicide may have had a mental illness (Cavanagh, Carson, Sharpe, & Lawrie, 2003). Research on state-level suicide rates have been found to be correlated with general mental health measures such as depression (Arsenault-Lapierre, Kim, & Turecki, 2004). While most people with mental health problems do not attempt or die by suicide (Olfson, Gerhard, Huang, Crystal, & Stroup, 2015) (and most people who attempt suicide do not die by suicide (Suominen et al., 2004)), assuring access to quality mental health care is critical to suicide prevention.

### Approaches

A major approach to strengthening access to mental health care is to have health insurance policies that include coverage for such services.

- **Coverage of mental health conditions in health insurance policies.** Health insurance policies that allow people with mental health problems to access mental health treatment in the same way that they access health care for physical health concerns can increase use of mental health services, help normalize treatment seeking in the population, reduce symptoms of mental illnesses like depression and bipolar disorder, and in turn, reduce rates of suicide and suicide attempts.

### Potential Outcomes

- Increased access to mental health services
- Decreased symptoms of mental illnesses
- Decreased rates of suicide attempts
- Decreased rates of suicide

### Evidence

Research suggests that policies supporting health insurance coverage of mental healthcare are associated with decreased suicide rates.

- **Coverage of mental health conditions in health insurance policies.** Using data from the National Survey of Drug Use and Health, Harris, Carpenter, and Bao (2006) found that 12 months after states enacted *mental health parity laws*, self-reported use of mental healthcare services significantly increased. Subsequent research by Lang (2013), suggests that mental health parity laws are associated with an approximate 5% reduction in suicide rates. This reduction (in 29 states) equated to the prevention of 592 suicides per year and a cost savings of \$1.3-3.1 million per suicide prevented (Lang, 2013).

## Establish Protective Environments

### Rationale

Suicide prevention efforts that focus on *both* the individual *and* his/her environment increase the likelihood of lives saved. Establishing protective environments helps ensure that all of the places where individuals live, work, and play are supportive. Limiting access to lethal means, be it at home or in nature, and particularly when an individual may be most vulnerable, can literally make the difference between life and death. Likewise, creating a work environment conducive to prevention and focused on employee well-being supports the large majority of the population where they spend much of their day. Finally, policies that reduce the availability of alcohol, a potent suicide risk factor, serve to further support individuals and protect the environment in which they live.

### Approaches

The current evidence suggests three approaches with promise for creating environments that protect against suicide.

- **Means Restriction.** Modifying the environment to decrease access to lethal means is an important public health strategy for preventing suicide. Acute suicidal crises are often brief and impulsive. Previous research indicates that the interval between thinking about suicide and attempting can be as short as 5-10 minutes (Deisenhammer et al., 2009; Simon et al., 2001). Getting past the impulse by making it more difficult to access lethal means can be lifesaving. Highly lethal means such as firearms, hanging/suffocation, or jumping from heights provide little opportunity for rescue and have high fatality rates (e.g., about 85% of people who use a firearm in an attempt die from their injury). Research also indicates that most people tend not to substitute a different method when a highly lethal method is unavailable or difficult to access (Hawton, 2007; Yip et al., 2012). Removing or restricting access to lethal means changes the context of the potential suicide and whether the outcome will be fatal or non-fatal (Yip et al., 2012).
  - *Intervening at Suicide Hotspots.* These interventions are focused on preventing suicides at locations which offer direct means for suicide or a secluded place that prevents intervention. Suicide hotspots include tall structures (e.g., bridges and cliffs), railway tracks, and isolated locations that are popular destinations for suicide (for example, parks). Interventions include barriers to prevent jumping and signs and telephones to encourage suicidal individuals to seek help (Cox et al., 2013).
  - *Safe Storage Practices* for medications, firearms, and other household products can reduce the risk for suicide by preventing impulsive action and separating individuals from easy access to lethal means. Safe storage practices include education and

counseling around storing firearms locked in a secure place (e.g., in a gun safe or lock box), preferably unloaded and separate from the ammunition. Keeping medicines in a locked cabinet or secure location can also prevent their misuse by children and adolescents (Rowhani-Rahbar, Simonetti, & Rivara, 2016; C. W. Runyan et al., 2016).

- **Organizational policies and culture** that focus on prosocial behavior, skill building, changing social norms, referral and access to helping services (e.g. mental health, substance abuse treatment, financial counseling), and that have leadership support from the top down can positively impact organizational climate and morale and help prevent suicide and its related risk factors (e.g. depression, social isolation).
  - *Together for Life* is a workplace program of the Montreal Police Force implemented to address suicide among officers. Policy and program components of *Together for Life* were designed to foster an organizational culture that promoted mutual support and solidarity among members of the Force, help for problems related to suicide, training of supervisors, managers and all units to improve competencies in identifying suicidal risk and in using existing resources, and an education campaign to improve awareness and help-seeking (Mishara & Martin, 2012).
  - The *United States Air Force Suicide Prevention Program (AFSPP)* serves as an example of an organizational policy inclusive of 11 policy and education initiatives that was designed to change the culture of the Air Force surrounding suicide. The program uses leaders as role models and agents of change, establishes expectations for behavior related to awareness of suicide risk, develops population skills and knowledge (i.e., education and training), and investigates every suicide (i.e., outcomes measurement). The program represents a fundamental shift from viewing suicide and mental illness solely as medical problem and instead sees them as larger service-wide problems impacting the whole community (K. L. Knox, Litts, Talcott, Feig, & Caine, 2003).
- **Community-based policies to reduce excessive alcohol use.** Acute alcohol use has been found to be associated with more than one-third of suicides and approximately 40% of suicide attempts (Cherpitel, Borges, & Wilcox, 2004). While various community policies exist to reduce excessive alcohol use (e.g., zoning limits related to alcohol outlet locations and density, taxes on alcohol, and bans on the sale of alcohol for individuals under the legal drinking age), previous research indicates that policies related to outlet locations and density are more strongly associated with suicide, making these particular policies an important approach to preventing suicide.

## Potential Outcomes

- Increase in safe storage of lethal means
- Reduction in suicide attempts
- Reduction in suicide deaths
- Reduction in alcohol-related suicide deaths

## Evidence

The evidence for the effectiveness of means restriction and other ways to establish protective environments is some of the strongest in the field (Zalsman et al., 2016).

- **Means restriction.** A meta-analysis of *suicide hotspot interventions* implemented in combination or in isolation in the U.S. and abroad found that they reduced suicide (Cox et al., 2013; Pirkis et al., 2015). For example, the suicide rate from jumping from the Jacques-Cartier bridge in Canada decreased significantly from 0.324 to 0.079 per 100,000 after the installation of a bridge barrier, or from about 10 suicide deaths to 2.6 per year (Perron, Burrows, Fournier, Perron, & Ouellet, 2013). Importantly, the reduction in suicides from the bridge was sustained when all bridges and nearby jumping sites were considered, suggesting little to no displacement of suicides to other jumping sites (Perron et al., 2013). In contrast, a study of the removal of safety barriers from the Grafton Bridge in Auckland, New Zealand demonstrated the negative impact of removing suicide hotspot interventions on preventing suicide (Beautrais, Gibb, Fergusson, Horwood, & Larkin, 2009). The removal of the Grafton Bridge barriers resulted in an immediate, substantial, and statistically significant increase in suicide by jumping from the bridge. Both the suicide numbers and rate saw a fivefold increase after the removal of the bridge barriers (Beautrais, 2001; Beautrais et al., 2009).

Another form of means restriction involves implementation of *safe storage practices*. In a case-control study of firearm-related events identified by medical examiner and coroner offices from 37 counties in Washington, Oregon, and Missouri, and 5 trauma centers, Grossman et al. (2005) found that *safe storage practices* (i.e., storing firearms unloaded, separate from ammunition, in a locked place and/or secured with a safety device) were protective for suicide attempts among adolescents. A recent systematic review of clinic and community-based education and counseling around safe storage of firearms found that the provision of safety devices significantly increases safe firearm storage practices compared to counseling alone or providing economic incentives to acquire safety devices (Rowhani-Rahbar et al., 2016). The *Emergency Department Counseling on Access to Lethal Means (ED CALM)* program trained psychiatric emergency clinicians in a large children's hospital to provide lethal means counseling and safe storage boxes to parents of patients under age 18 receiving care for suicidal behavior. In a pre-post study, (C. W. Runyan et al., 2016) found that among the parents contacted at follow-up, 76% reported all medications in the home were locked up as compared to fewer than 10% at the time of the initial emergency department visit. Among

parents who indicated the presence of guns in the home at the time of the child's initial emergency department visit, all reported guns were currently locked, compared to 67% reporting this at the time of the initial visit (C. W. Runyan et al., 2016).

- **Organizational policies and culture.** After implementation of the *Together for Life* program, police suicides were tracked over 12 years and compared to rates in the control city of Quebec. Pre-post assessments of learning, interviews, and focus groups were also included. The suicide rate in the intervention group decreased significantly by 78.9% to 6.42 per 100,000 per year compared to 29.0 per 100,000 in the control city (Mishara & Martin, 2012).

Additionally, using a time-series design to examine the impact of the AFSP program on various violence-related outcomes, researchers found that the program was associated with a 33% relative risk reduction in suicide (K. L. Knox et al., 2003). The program was also associated with relative risk reductions in related outcomes including moderate and severe family violence (30% and 54%, respectively), homicide (51%), and accidental death (18%) (K. L. Knox et al., 2003). A longitudinal assessment of the program over the period 1981 to 2008 (16 years before the 1997 launch of the program and 11 years post-launch) found significantly lower rates of suicide after the program was launched than before (K. L. Knox et al., 2010). These effects were sustained over time, except in 2004, which the authors found was associated with less rigorous implementation in that year than in the other years (K. L. Knox et al., 2010).

- **Community-based policies to reduce excessive alcohol use.** Several studies on alcohol outlet density suggest that *measures to reduce alcohol outlet density* can potentially reduce alcohol-involved suicides. Research studies in the United States have found that greater alcohol availability is positively associated with alcohol-involved suicides (Escobedo & Ortiz, 2002; Giesbrecht et al., 2015). For example, Giesbrecht et al. (2015) found that both on and off-premises alcohol outlets (i.e., restaurants where alcohol is served and stores where alcohol is available for purchase to go) were positively associated with alcohol-related suicides in 14 U.S. states, particularly among men (AOR 1.08, CI=1.03-1.13) and American Indian/Alaska Natives (AOR= 1.36; CI= 1/10-1.69). Additionally, a longitudinal analysis of alcohol outlet density, suicide mortality, and hospitalizations for suicide attempts over 6 years in 581 California zip codes indicated that the density of bars, specifically, is related to suicide and suicide attempts, particularly in rural areas (Johnson, Gruenewald, & Remer, 2009).

## Promote Connectedness to Protect Against Suicide

### Rationale

The quantity and quality of our social connection with others has been linked with suicide dating as far back to Durkheim, who first posited that weak social bonds are among the chief causes for suicidality (Durkheim, 1951). Connectedness is the degree to which an individual or group of individuals are socially close, interrelated, or share resources with others (Centers for Disease Control and Prevention, 2009), and social connections can be formed within and between multiple levels of the social ecology (Dahlber & Krug, 2002) for instance between individuals (e.g. peers, neighbors, co-workers), families, schools, neighborhoods, workplace, faith communities, cultural groups, and society as a whole. Related to connectedness, social capital refers to a sense of trust in one's community and neighborhood, social integration, and also the availability and participation in social organizations (Beyer, Layde, Hamberger, & Laud, 2015; Muennig, Cohen, Palmer, & Zhu, 2013). Many ecological cross-sectional and longitudinal studies have examined the impact of aspects of social capital on depression symptoms, depressive disorder, mental health more generally, and suicide. While the evidence is still being built the pattern is towards an inverse association between social capital measured by social trust, community/neighborhood engagement, and improved mental health. Connectedness and social capital together can serve to protect against suicidal behaviors by decreasing isolation, encouraging adaptive coping behaviors, increasing belongingness, personal value and worth all of which helps individuals to build resilience in the face of adversity. Connectedness can also provide individuals with better access to formal supports and resources, mobilize communities to meet the needs of its members and provide collective primary prevention activities to the community as a whole (Centers for Disease Control and Prevention, 2009)

### Approaches

Promoting connectedness among individuals and within communities through modeling peer norms and enhancing community engagement can protect against suicide.

- **Peer norm approaches** seek to normalize help-seeking, encourage reaching out and talking to trusted adults, and promote supporting peers through building connectedness. These approaches are typically delivered in school settings but can also be implemented in community settings.
  - *Sources of Strength* is a suicide prevention program for adolescents (ages 13-17) and young adults (ages 18-25) that uses peer social networks to enhance protective factors and change unhealthy norms and behavior. The program trains young people to serve as peer leaders and connects them with adult advisors at school and in the community.

Peer leaders are taught to use their leadership qualities and social influence to promote strength-based messages intended to change peer group norms around coping practices and problem behaviors (e.g., self-harm, substance use, and unhealthy sexual practices). The goal of the program is to reduce the acceptability of suicide as a response to distress, increase the acceptability of seeking help, improve communication between youth and adults, and to develop healthy coping attitudes and behaviors among youth (Wyman, 2014).

- **Community engagement activities.** Community engagement is an aspect of social capital and involves residents participating in a range of activities, including religious activities, community clean-up and greening activities, and physical exercise. These activities provide opportunities for residents to become more involved in the community and to connect with other community members, organizations, and resources, resulting in enhanced overall physical health, reduced stress, and decreased depressive symptoms, thereby reducing risk of suicide.
  - *Greening vacant urban spaces.* Many cities across the nation have experienced urban abandonment over time or in response to the Great Recession (2007-2009). Some of these communities have sought to engage community members in the cleaning and greening of vacant lots. These activities bring community residents together to clean and beautify vacant areas – sometimes building playgrounds and walking areas and other times merely cleaning up litter and mowing the lawns of abandoned homes. Such activities foster community engagement, prosocial norms, and social cohesion, protective factors for suicide (Branas et al., 2011).

### Potential Outcomes

- Reduction in maladaptive coping attitudes and behaviors
- Increase in healthy coping attitudes and behaviors
- Increase in referrals for youth in distressed
- Increase help-seeking behaviors
- Positive perception of adult support

### Evidence

Current evidence provides some support indicating that peer norm approaches and community engagement can reduce risk factors associated with suicidal behaviors.

- **Peer norm approaches.** Evaluations show that programs such as *Sources of Strength* can improve school norms and beliefs about suicide that are created and disseminated by student peers. In a randomized controlled trial of *Sources of Strength* conducted with 18 high-schools

(6 metropolitan, 12 rural), Wyman et al. (2010) found that the program improved peer leaders' adaptive norms regarding suicide, their connectedness to adults, and school engagement. Peer leaders were also more likely than controls to refer a suicidal friend to an adult. Among students, the intervention increased perceptions of adult support for suicidal youths and the acceptability of seeking help. Perception of adult support increased most in students with a history of suicidal ideation. Finally, trained peer leaders also reported a greater decrease in maladaptive coping attitudes compared with untrained leaders (Wyman et al., 2010).

- **Community engagement activities.** One vacant lot greening initiative was undertaken in Philadelphia between 1999 and 2008. Local residents and community members worked together to green 4,436 lots in 4 areas of Philadelphia, PA, resulting in significant reductions in community residents' self-reported stress levels and engagement in more physical exercise than residents in control vacant lot areas. Other benefits included reductions in firearm assaults and vandalism (Branas et al., 2011).

## Teach Coping and Problem-Solving Skills

### Rationale

Building life skills prepare individuals to successfully tackle every day challenges and adapt to stress and adversity. Life skills encompasses many concepts, but most often include coping and problem-solving skills, conflict resolution, and critical thinking. Life skills are important in shielding individuals from suicidal behaviors (World Health Organization, 2014). Suicide prevention programs that focus on life and social skills training are drawn from social cognitive theories (Bandura, 1986), surmising that individuals who engage in suicidal behavior is attributed to either direct learning, modeling, and environmental and individual (e.g. hopelessness) characteristics. The literature linking life skills and suicide is robust--- The inability to employ adequate coping strategies to cope with immediate stressors or identify and find solutions for problems have been characterized among suicide attempters (Pollock & Williams, 2004). Treatments that include bolstering problem skills (Goldsmith, Pellmar, Kleinman, & Bunney, 2002) and include problem-solving techniques (Ghahramanlou-Holloway, Bhar, Brown, Olsen, & Beck, 2012; Townsend et al., 2001) appear to reduce suicidal ideation and attempts more effectively. Prevention programs focused on teaching these skills target youth, parents and families and have been used with both universal and at-risk populations. While many do not target suicidal behaviors directly, these programs strive to train youth and parents important life skills to offset the underlying vulnerabilities that contribute to engaging in high risk behaviors early in life.

### Approaches

Current evidence provides support for the following two approaches:

- **Social emotional learning programs** focus on developing and strengthening communication and problem-solving skills, emotion regulation, conflict resolution, help seeking and coping skills. These approaches address a range of risk and protective factors for suicidal behavior. They provide children and youth with skills to resolve problems in relationships, school, and with peers, and help youth to address other negative influences (e.g., substance use) associated with suicide. These approaches are typically delivered to all students in a particular grade or school, although some programs also focus on groups of students considered to be at high-risk for suicide. Opportunities to practice and reinforce skills are an important part of programs that work (Herman, Borden, Reinke, & Webster-Stratton, 2011).
  - *The Youth Aware of Mental Health Program (YAM)* teaches youth about the risk and protective factors associated with suicide (including knowledge about depression and anxiety), and helps enhance their problem-solving skills for dealing with adverse life events, stress, school and other problems. The program includes 3 hours of role-play sessions with interactive workshops combined with a booklet that students take home, educational

posters displayed in classroom, and interactive lectures about mental health at the beginning and end of the program (Wasserman et al., 2014).

- *Signs of Suicide (SOS)* is a school-based prevention program for students ages 13-17. The program includes guided classroom discussions about suicide and depression. As part of the program, students are screened for depression and suicide risk and referred for professional help as indicated. The program is designed to increase knowledge about suicide and risk factors associated with suicidal behavior as well as improve and normalize help-seeking behavior (Schilling, Aseltine, & James, 2016).
- *The Good Behavior Game (GBG)* is a classroom-based program for elementary school children ages 6-10. The program uses a team-based behavior management strategy that promotes good behavior by setting clear expectations for good behavior and consequences for maladaptive behavior. The goal of the GBG is to create an integrated classroom social system that is supportive of all children being able to learn with little aggressive or disruptive behavior (Wilcox et al., 2008).
- **Parenting skill and family relationship programs** are designed to strengthen parenting skills, enhance positive parent-child interactions, and improve children's behavioral and emotional skills and abilities. Several parenting and family relationship programs have been shown in rigorous evaluations to improve resilience and reduce risk factors for various behaviors, including ones closely related to suicide, such as depression, internalizing behaviors, and substance abuse (M. S. Knox, Burkhart, & Hunter, 2010).
  - *The Incredible Years* is a comprehensive group training program for parents, teachers and children is designed to prevent and treat behavioral and emotional problems in children ages 2-12. The program includes 9- 20 sessions (depending on the age of the child) offered in community based settings (e.g., religious, recreation centers, mental health treatment centers, hospital medical centers). Its goal is to reduce conduct and substance abuse problems, two important suicide risk factors in youth, by improving protective factors such as responsive and positive parent-teacher-child interactions and relationships, emotion self-regulation and social competence (all protective factors for suicide) (Herman et al., 2011).
  - *Strengthening Families 10-14 years* is a program that involves sessions between parents, youth, and family with the goal of improving parents' skills for disciplining, managing emotions and conflict, and communicating with their children; promoting youths' interpersonal and problem-solving skills; and creating family activities to build cohesion

and positive parent-child interactions. The premise of the program is that developing of these skills for both parents and children will reduce internalizing behavior and adolescent substance abuse, two important risk factors for suicide (Spoth, Gyll, & Day, 2002).

### Potential Outcomes

- Reduction in suicide attempts and suicide ideation
- Enhanced knowledge of risk and protective factors associated with suicide
- Reduction in suicide risk behaviors (i.e., depression, anxiety, conduct problems, substance abuse)
- Improve and normalize help-seeking behavior
- Enhance social competence and emotional regulation skills
- Enhance problem-solving and conflict management skills

### Evidence

There are a several programs with evidence that supports teaching social, emotional and parenting skills to reduce suicidal behaviors and associated risk factors.

- **Social emotional learning programs.** In a cluster-randomized controlled trial of *YAM* conducted across 10 European Union countries and 168 schools, students participating in the *YAM* program were significantly less likely to have an incident suicide attempt (OR 0.45, 95%CI 0.24–0.85;  $p=0.014$ ) and severe suicidal ideation (0.50, 0.27-0.92;  $p=0.025$ ) at the 12-month follow-up compared to the control group. Additionally, related to severe suicide ideation, in the *YAM* group absolute risk fell by 0.50% and RR fell by 49.6% (Wasserman et al., 2014).

Additionally, in a randomized controlled trial, *SOS* was shown to reduce self-reported suicide attempts at 3-months post intervention among participating students compared to control students. The *SOS* program also increased students' knowledge of how to get help for themselves or friends for depression and/or suicidal thoughts, and favorable attitudes toward help-seeking. *SOS* participants with a lifetime history of suicide attempt were also less likely to report planning a suicide in the 3 months following the program compared to lower-risk participants (Schilling et al., 2016).

Finally, in an outcome evaluation of the *GBG*, first graders assigned to *GBG* reported half the adjusted odds of suicidal ideation and suicide attempts. The beneficial effect of the program was consistent for suicidal ideation regardless of whether baseline covariates were included. The *GBG* effect on attempts was less robust in some adjusted models including caregiver mental health. In the second cohort of *GBG* students, neither suicidal ideation nor

suicide attempts were significantly different between *GBG* and the control interventions (Wilcox et al., 2008). This finding likely arose due to the lack of implementation fidelity and pointed to the need for *GBG* to be delivered with precision, consistency, and teacher support. *GBG* was also found to be associated with reduced risk of later substance abuse, a risk factor for suicide (Kellam et al., 2008).

- **Parenting skill and family relationship programs.** Parenting and family skills training approaches have shown promising impacts in preventing key risk factors associated with suicide. Several studies have demonstrated the effect of *The Incredible Years* program on reducing internalizing symptoms, such as anxiety and depression, and child conduct problems (C. H. Webster-Stratton, Reid, & Beauchaine, 2011; Webster-Stratton, Jamila Reid, & Stoolmiller, 2008). The program is also associated with improved problem-solving and conflict management; these skills were maintained at 1-year follow-up (Reid, Webster-Stratton, & Hammond, 2003; C. Webster-Stratton & Hammond, 1997; C. Webster-Stratton, Reid, & Hammond, 2001). The program demonstrated greater benefits as the dosage of the intervention increased (Herman et al., 2011).

Additionally, *Strengthening Families* has been shown to decrease externalizing behaviors, alcohol use, and drug use among youth participants and reductions in depression, alcohol use, and drug use among participating families (Spoth et al., 2002).

## Identify and Support People At-Risk

### Rationale

In order to be successful in decreasing suicidal behavior, attention must be paid to those who are at-risk or vulnerable. These persons experience risk and occurrence of suicidal behavior at higher than average rates. This group requires particular focus on proactive case finding and retention and access to services. These vulnerable or disadvantaged populations include, but are not limited to, individuals living in lower socio-economic status or with a mental health problem; individuals who are institutionalized, have been victims of violence, or are homeless; and members of certain ethnic minority groups. Finding effective ways of identifying at-risk or vulnerable groups, customizing services to make them accessible and maintaining care are still key challenges. For example, simply improving services does not guarantee that those services will be used by those most in need of them, nor will it necessarily increase the number of people who follow treatments that are recommended. People who are disadvantaged face social and economic issues that may adversely affect their ability to respond to the treatments or advice that are offered.

### Approaches

This document outlines three approaches that focus on identifying and supporting those who are at-risk.

- **Gatekeeper training** is typically implemented in schools and within health care settings and is designed to train teachers, coaches, providers and others in the community to identify people who may be at risk of suicide and to respond effectively, including facilitating treatment seeking and support services.
  - *Mental Health First Aid (MHFA)*, designed for the lay public, consists of three weekly sessions of three hours each. The content covers helping people in mental health crises and/or in the early stages of mental health problems. The crisis situations covered included suicidal thoughts and behavior, acute stress reaction, panic attacks and acute psychotic behavior. The mental health problems discussed included depressive, anxiety and psychotic disorders. The co-morbidity with substance use disorders is also covered. Participants learn the symptoms of these disorders, possible risk factors, where and how to get help and evidence-based effective help (Kitchener & Jorm, 2004).
- **Screening combined with care management and overall continuity of care** has been used in primary care and behavioral health care to assure that people who may be at high-risk of suicide don't 'slip through the cracks'. These approaches typically employ screening for

depression and/or suicide combined with collaborative treatment planning between patients and their providers and patient follow-up. Programs such as these have demonstrated beneficial effects on depression, suicide ideation, and suicide mortality.

- *Henry Ford Perfect Depression Care (Pre-cursor to Zero Suicide)*. The overall goal of the Henry Ford Perfect Depression Care program was to eliminate suicide. More broadly, the aim of the program was to completely redesign depression care delivery to achieve breakthrough improvement in quality and safety. The redesign focused on six aims: effectiveness, safety, patient centeredness, timeliness, efficiency, and equity among patients. The program developed concrete measures to assess progress on each of these aims. The program began with screening and assessment of each patient for suicide risk with coordinated continuous follow-up care system wide (C. E. Coffey, 2006).
- **Crisis intervention.** These approaches provide support and referral services, typically by connecting a person in crisis (or a friend or family member of someone at-risk) to trained volunteers and/or professional staff via telephone hotline, online chat, or text messaging. Crisis intervention approaches are intended to impact key risk factors for suicide, including feelings of depression, hopelessness, and subsequent mental health care utilization. Like means restriction, crisis interventions can put space or time between an individual who may be considering suicide and harmful behavior.
  - *National Suicide Prevention Lifeline (NSPL)*. This is a nationwide hotline that operates 24/7 and is accessible by phone or a web-based chat function. Trained counselors are on-hand to listen, offer free and confidential emotional support, and provide referrals for mental health services in the local area (Gould, Cross, Pisani, Munfakh, & Kleinman, 2013).
  - *Applied Suicide Intervention Skills Training (ASIST)*. This a training program for hotline counselors, emergency workers, clergy, caregivers and others in the community. The ASIST model has three phases of caregiving: connecting, understanding and assisting. The training helps participants identify people who are having thoughts of suicide and to recognize their invitation for help (connecting); to listen to the caller's reasons for dying and living (understanding); and how to conduct a safety assessment, develop a safety plan for the person at risk, and connect the person at risk to community resources (assisting). The ASIST training program has been field tested in a variety of settings (Gould et al., 2013).

### Potential Outcomes

- Reduction in suicide attempts
- Reduction in suicide deaths
- Increased identification of individuals at-risk for suicidal behavior
- Increased at-risk individuals in treatment
- Increased community members trained to identify at-risk individuals
- Increased referrals for health care

### Evidence

There is evidence that community gatekeeper programs are successful in reducing suicides and suicide attempts but the efforts must be maintained (Substance Abuse and Mental Health Services Administration, Center for Mental Health Services. Report to Congress: Garret Lee Smith Suicide Prevention Program. US Department of Health and Human Services: Rockville, MD, 2014). However, there is limited evidence for effectiveness screening programs, but at the same time, standard principles for public health screening make them promising (Pena & Caine, 2006). The number of studies evaluating crisis intervention services is limited, but a few studies do indicate that those who use the hotline services have decreased suicidal thoughts and behavior.

Comment [A]: Need to add ref

- **Gatekeeper training.** In a randomized controlled trial of 300 participants of *Mental Health First Aid (MHFA)*, the intervention group reported greater confidence in providing help to others, greater likelihood of advising people to seek professional help, improved concordance with health professionals about treatments, and decreased stigmatizing attitudes. Additionally, the intervention resulted in improved mental health of the participants themselves. All results were statistically significant at  $p < .05$ . (Kitchener & Jorm, 2004). Additional research rigorously evaluating *MHFA* for its impact on the first aid recipients themselves and suicidal behavior is needed (Kitchener & Jorm, 2006).
- **Screening combined with care management and overall continuity of care.** An examination of the impact of the *Henry Ford Perfect Depression Care (Pre-cursor to Zero Suicide)* program found that there was a dramatic and statistically significant decrease in the rate of suicide between the baseline years prior to the intervention (1999 and 2000) to the intervention years (2002-2009). During this time period, the suicide rate fell 82% (C. E. Coffey, 2006; C. E. Coffey, Coffey, & Ahmedani, 2013). Further, suicide rates also declined among HMO members who participated in targeted suicide prevention efforts and received mental health specialty services. However, for those HMO members who accessed only general medical services as opposed to specialty mental health services, the suicide rate increased (M. Coffey, Coffey, & Ahmedani, 2015).

- **Crisis intervention.**

*National Suicide Prevention Lifeline (NSPL).* In an evaluation of the effectiveness of the National Suicide Prevention Lifeline (NSPL) to prevent suicide, 1,085 suicidal individuals who called the hotline completed a standard risk assessment for suicide, and 380 of those completed a follow-up assessment between 1 and 52 days after the initial assessment. Researchers found that over half of the initial sample were seriously considering suicide when they called, and they had a plan for their suicide. At the same time, researchers found that participants experienced significant decreases in suicidality over the course of the telephone session, and their levels of hopelessness and psychological pain continued to decrease after their initial call (Gould, Kalafat, Harrismunfakh, & Kleinman, 2007).

*Applied Suicide Intervention Skills Training (ASIST).* The ASIST training program has been field tested in a variety of settings. In a national randomized controlled trial, Gould et al. (2013) assessed the impact of the ASIST training across the NSPL network of hotlines over the period 2008-2009. Using data from 1,410 suicidal individuals who called 17 Lifeline centers, researchers found that compared to callers who spoke to counselors that received the usual care training, individuals who spoke with counselors trained in ASIST were significantly more likely to feel less depressed, less suicidal, less overwhelmed, and more hopeful by the end of their call to the hotline. Counselors trained in ASIST were also more skilled at keeping callers on the phone longer and establishing a connection with them. However, training in ASIST did not result in more comprehensive suicide risk assessments than usual care training (Gould et al., 2013).

## Intervene to Lessen Harms and Prevent Future Risk

### Rationale

Individuals who have experienced mental health challenges, suicidal ideation, and have had non-fatal suicide attempts or have engaged in non-suicidal self-injury are at increased risk of subsequent suicide-related morbidity and mortality. Risk of suicidality can also increase among those who have lost a friend, family member, co-worker, or other acquaintance to suicide. Exposure to sensationalized or uninformed reporting regarding suicide-related deaths may heighten the risk of suicide among vulnerable individuals and can inadvertently contribute to suicide contagion.

### Approaches

A broad array of approaches to lesson harms and reduce future risk of suicidality among those at increased risk include the provision of mental health care and improved continuity of care, improving linkage to care through active post-discharge planning and follow-up that decreases barriers to ongoing therapeutic support, increasing connectedness to supportive others, addressing bereavement, and framing communications to emphasize resilience, decrease negative affect, and to prevent contagion.

- **Treatment for people at-risk of suicide** typically includes various forms of psychotherapy delivered by licensed providers to help individuals with mental health problems and other risk factors for suicide with problem-solving, impulsivity and emotion regulation.
  - *Improving Mood – Promoting Access to Collaborative Treatment (IMPACT)* aims to prevent suicide among older primary care patients by reducing suicide ideation and depression in primary care settings. IMPACT facilitates the development of a therapeutic alliance, a personalized treatment plan that includes patient preferences, as well as proactive follow-up (biweekly during an acute phase and monthly during continuation phase) by a depression care manager (Hunkeler et al., 2006).
  - *Collaborative Assessment and Management of Suicidality (CAMS)* is a therapeutic framework for suicide-specific assessment and treatment of patient's suicide risk. It is a flexible approach that can be used across treatment settings and clinician theoretical orientations. The clinician and patient work together in an interactive assessment process. The patient is highly engaged in the development of their own treatment plan. Every session of CAMS is collaborative and involves the patient's input about what is and is not working. Ultimately, this process is designed to enhance the therapeutic alliance and increase treatment motivation in the suicidal patient (Jobes, 2012).

- *Dialectical Behavioral Therapy* is a multicomponent therapy for individuals at high risk for suicide who may struggle with impulsivity and emotional regulation. The components of DBT include individual therapy, group skills training, between-session telephone coaching and a therapist consultation team.
- *Attachment-Based Family Therapy (ABFT)* is a program for adolescents ages 12-18 that is designed to treat clinically diagnosed major depressive disorder, eliminate suicidal ideation, and reduce dispositional anxiety (Diamond et al., 2010).
- **Treatment to prevent re-attempts.** These follow-up contact approaches use diverse modalities (e.g., home visits, mail, telephone, e-mail) to engage recent suicide attempt survivors to prevent reattempts. These approaches typically focus on coping and other emotional regulation skills and may include case management home visits to increase adherence to and continuity of care, one-on-one interpersonal therapy and/or group therapy. Approaches that engage and connect attempters to peers and providers are especially important because many attempters do not present to aftercare; 12%-25% reattempt within a year, and 3%-9% of attempt survivors die by suicide within 1 to 5 years of their initial attempt (Inagaki et al., 2015)
  - *Emergency Department Brief Intervention with Follow-up Visits* - A one-hour discharge information session that addressed suicidal behavior, distress, risk and protective factors, alternatives to suicidal behavior, and referral options was combined with nine follow-up contacts over 18-months (at 1, 2, 4, 7, 11 weeks and 4, 6, 12, 18 months). Follow-up contacts were either conducted by phone or home visits according to a specific time line for up to 18-months.
  - *Active follow-up contact approaches* such as postcards, letters, and telephone calls, are intended to increase a patient's sense of connectedness with health care providers and decrease isolation. These approaches include expression of caring and support and typically invite patients to reconnect with their provider. Contacts are made periodically (e.g., monthly or every few months in the first 12 months post-discharge with some programs continuing contact for 2 or more years).
  - *Cognitive Behavior Therapy for Suicide Prevention (CBT-SP)* uses a risk reduction, relapse prevention approach that includes an analysis of proximal risk factors and stressors (e.g., relationship problems, school or work-related difficulties) leading up to and following the suicidal event; safety plan development; skill building; and psychoeducation. *CBT-SP* also has family skill modules focused on family support and communication patterns as well as improving the family's problem solving skills.

- **Postvention** approaches are implemented after a suicide has taken place and may include debriefing of survivors (those who have lost a friend, peer, family member, co-worker to suicide), counseling, and/or bereavement support groups. The programs have not typically tested their impact on suicide or suicidal behavior but may reduce risk of guilt, feelings of depression, and complicated grief (Szumilas & Kutcher, 2011). Additionally, research suggests that active postvention approaches in which outreach to suicide survivors occurs at the scene of a suicide is associated with intake into treatment sooner, greater attendance at support group meetings, and attendance at more meetings compared to passive postvention (no outreach) (Cerel & Campbell, 2008).
  - *StandBy Response Service* is a suicide bereavement support service. The service provides clients with face-to-face outreach and telephone support provided by a professional crisis response team. A site coordinator then develops a customized case management plan, referring clients to other existing community services matched to their needs (Visser, Comans, & Scuffham, 2014).
- **Safe messaging following a suicide.** The manner in which information on a recent suicide is communicated to the public (e.g. school assemblies, mass media, social media) can heighten the risk of suicide among vulnerable individuals and can inadvertently contribute to suicide contagion.
  - *Media guidelines.* Guidelines for reporting on suicides can help assure that stories on suicide are communicated in a safe and effective way. Reports that are both inclusive of suicide prevention messages, stories of hope and resilience, risk and protective factors, and links to helping resources (e.g., hotline) and that avoid sensationalizing events or reducing suicide to one cause can help reduce the likelihood of suicide contagion (Niederkrotenthaler & Sonneck, 2007).

### Potential Outcomes

- Reduction in mental health-related sequelae
- Increase connectedness
- Improved coping skills
- Improved messaging following suicide
- Reduction in re-attempts

## Evidence

The evidence addressing strategies to lesson harm and prevent future risk of suicide includes the evaluation of effects of specific approaches on risk and protective factors as well as suicide-related mortality. However, because the evaluation of suicide-related mortality is a statistically rare event, evaluation of mortality outcomes requires large sample sizes and extended follow-up. Therefore, much of the evidence in this area primarily focuses on risk and protective factors.

- **Treatment for people at-risk of suicide.**

**Improving Mood – Promoting Access to Collaborative Treatment (IMPACT)** has been shown to significantly improve quality of life, and to reduce functional impairment, depression and suicidal ideation over 24-months of follow-up (Hunkeler et al., 2006; Unutzer et al., 2006) relative to patients who received care as usual.

**Collaborative Assessment and Management of Suicidality (CAMS)** has been tested and supported in 6 correlational studies (Jobes, 2012), in a variety of inpatient and outpatient settings and in one RCT with several additional RCTs under way. CAMS has been associated with significant improvements in suicidal ideation, overall symptom distress, and feelings of hopelessness at 12 month follow-up among a community-based sample of suicidal outpatients. (Comtois et al., 2011).

**Dialectical Behavioral Therapy.** In a randomized controlled trial of women with recent suicidal or self-injurious behavior, those receiving DBT were half as likely to make a suicide attempt at two-year follow-up than women receiving community treatment (23% vs 46%), required less hospitalization for suicide ideation, and had lower medical risk across all suicide attempts and self-injurious acts combined (Linehan et al., 2006).

**Attachment-Based Family Therapy (ABFT).** A randomized controlled trial of ABFT (Diamond et al., 2010) found that suicidal adolescents assigned to ABFT experienced significantly greater improvement in suicidal ideation over 24 weeks of follow-up than did adolescents assigned to enhanced usual care (-4.37 vs. -2.34;  $p = .001$ ;  $d=0.97$ ). Additionally, a higher percentage of ABFT participants reported no suicidal ideation in the week prior to assessment at 12 weeks than did adolescents receiving enhanced usual care (69.2% vs. 34.6%;  $p = .01$ ;  $OR= 4.25$ ) and at 24 weeks (82.1% vs. 46.2%;  $p = .006$ ;  $OR=5.37$ ) (Diamond et al., 2010).

- **Treatment to prevent re-attempts.**

**Emergency Department Brief Intervention with Follow-up Visits.** A randomized controlled trial that enrolled suicide attempters from eight hospital emergency departments in five culturally different sites found that a brief intervention combined with 9 follow-up visits over 18-months was associated with significantly fewer deaths from suicide relative to a treatment-as-usual group (0.2% versus 2.2%, respectively;  $\chi^2 = 13.83$ ,  $P < 0.001$ ) (Fleischmann et al., 2008).

**Active follow-up contact approaches** intended to prevent reattempts among patients that have been hospitalized and subsequently discharged for suicide attempts have been found in a meta-analysis conducted by Inagaki et al. (2015) to reduce reattempts by approximately 17% for up to 12 months post-discharge, however, the long-term effects of these approaches on reattempts has not yet been demonstrated. Also, because the number of trials and associated sample sizes included in this meta-analysis were small, it was not possible to determine the effect of active contact and follow-up approaches on death by suicide. In a randomized controlled trial of postcrisis suicide prevention long-term follow-up contact approach, Motto and Bostrom (2001) found that patients who refused ongoing care but who were randomized to be contacted by letter four times per year had a lower rate of suicide over two years of follow-up than did patients in the control group who received no further contact. Other studies have also shown post-crisis letters and coping cards to be protective against suicide ideation and attempts (Hassanian-Moghaddam, Sarjami, Kolahi, & Carter, 2011; Wang et al., 2016).

**Postvention.** In a study by Visser et al. (2014), *StandBy* clients were significantly less likely to be at high risk for suicidality than a suicide bereaved comparison group who had not had contact with the *StandBy* program (48% and 64% respectively,  $p = 0.005$ ).

**Safe messaging following a suicide.** The most compelling evidence supporting the effect of *media guidelines* on reduction in suicides comes from Austria. After a sharp increase in suicides on the Viennese subway, media guidelines were introduced and an interrupted time series design was used to evaluate the national impact of the guidelines on subsequent suicides. Changes in the quality and quantity of media reporting resulted in a reduction of 81 suicides annually (95% confidence interval: -149 to -13;  $t = -2.32$ ,  $df = 54$ ,  $p < 0.024$ ) in the Viennese subway system (Niederkrötenenthaler & Sonneck, 2007)

## Sector Involvement

Public health can play an important and unique role in addressing suicide. Public health agencies, which typically place prevention at the forefront of efforts and work to create broad population-level impact, can bring critical leadership and resources to bear on this problem. For example, these agencies can serve as a convener, bringing together partners and stakeholders to plan, prioritize, and coordinate suicide prevention efforts. Public health agencies are also well positioned to collect and disseminate data, implement preventive measures, evaluate programs, and track progress. Although public health can play a leadership role in preventing suicide, the strategies and approaches outlined in this technical package cannot be accomplished by the public health sector alone.

Other sectors vital to implementing this package include, but are not limited to, education, government (local, state, and federal), social services, health services, business/labor, justice, housing, media, and organizations that comprise the civil society sector such as faith-based organizations, youth-serving organizations, foundations, and other non-governmental organizations. Collectively, these sectors can make a difference in preventing suicide by impacting the various contexts and underlying risks that contribute to suicide.

The strategies and approaches described in this technical package are summarized in Appendix A along with the relevant sectors that are well positioned to lead implementation efforts.

[I can write the text specific to the strategies and approaches. I've done this for the other TPs and am happy to do the same here. This is the section where we distinguish the strategies where public health is best positioned to lead from those where leadership is necessary from other sectors and how public health can assist, etc.]

Regardless of strategy, action by many sectors will be necessary for the successful implementation of this package. In this regard, all sectors can play an important and influential role in creating safe and protective environments where individuals who are at high risk of suicide can easily access the mental healthcare and services they need.

## Monitoring and Evaluation

Monitoring and evaluation are necessary components of the public health approach to prevention. It is important to have timely and reliable data to monitor the extent of the problem and to evaluate the impact of prevention efforts. Data are necessary for program implementation; planning, implementation, and assessment all rely on accurate measurement of the problem.

Surveillance data helps researchers and practitioners track changes in the burden of suicide.

Surveillance systems exist at the federal, state, and local levels. It is important to assess the availability of surveillance data and data systems across these levels to identify and address gaps in the systems. CDC's National Vital Statistics System and the National Violent Death Reporting System (NVDRS) are examples of surveillance systems that provide data on deaths from suicide. NVDRS, for example, is a state-based surveillance system that combines data from death certificates, law enforcement reports, and coroner or medical examiner reports to provide detailed information on the circumstances of violent deaths, including suicide, which can assist communities in guiding prevention approaches (Blair, Fowler, Jack, & Crosby, 2016). The National Electronic Injury Surveillance System-All Injury Program (NEISS-AIP) provides nationally representative data about all types and causes of nonfatal injuries treated in U.S. hospital emergency departments, and can be used to assess national rates of, and trends in, self-harm injuries by cause (e.g., falls, poisoning, etc.), age, race/ethnicity, sex, disposition (where the injured person goes when released from the Emergency Department (<http://www.cdc.gov/injury/wisqars/nonfatal.html>)).

In addition to information on deaths and nonfatal injuries, there are also surveillance systems that provide national, state, and some local estimates of suicidal behavior. The Youth Risk Behavior Surveillance System (YRBSS) collects information from a nationally representative sample of 9-12 grade students and is a key resource in monitoring health-risk behaviors among youth, including whether youth have seriously considered attempting suicide, attempted suicide, made a plan, or required treatment by a doctor or nurse for a suicide attempt that resulted in an injury, poisoning, or overdose (Brener et al., 2013). The YRBSS data are obtained from a national school-based survey conducted by CDC as well as school-based state, territorial, tribal, and large urban school district survey conducted by education and health agencies. The National Survey on Drug Use and Health (NSDUH) is an annual nationwide survey of individuals aged 12 years and older that provides national and state-level estimates of drug use and mental health-related issues, including suicide ideation and suicide attempts (<https://nsduhweb.rti.org/respweb/homepage.cfm>).

It is also important at all levels (local, state, and federal) to address gaps in responses, track progress of prevention efforts and evaluate the impact of those efforts, including the impact of this technical package. Evaluation data, produced through program implementation and monitoring, is essential to provide information on what does and does not work to reduce rates of suicide and its associated risk

and protective factors. Theories of change and logic models that identify short, intermediate, and long-term outcomes are an important part of program evaluation.

The evidence-base for suicide prevention has advanced greatly over the last few decades. However, additional research is needed to understand the impact of prevention programs on preventing suicide, as opposed to merely examining the effectiveness of programs to impact risk factors associated with suicide. More research is also needed to examine the effectiveness of upstream and community-level strategies to prevent suicide at the population level. Lastly, it will be important for researchers to test the effectiveness of combinations of the strategies and approaches included in this package. Most existing evaluations focus on approaches implemented in isolation. However, there is potential to understand the synergistic effects within a comprehensive prevention approach. Additional research is needed to understand the extent to which combinations of strategies and approaches result in greater reductions in suicide than individual programs, practices, or policies.

## **Conclusion**

## References

(See last 7 pages after Appendix—EndNote put them there because it thought the Appendix/table was part of the regular text; Didn't want to cut and paste table for fear it'd get de-formatted)

## Appendix A: Summary of Strategies and Approaches to Prevent Suicide

Strategy	Approach/Program, Practice or Policy	Best Available Evidence			Lead Sectors <sup>1</sup>
		Suicide	Suicide Attempts or Ideation	Other Risk/Protective Factors for Suicide	
Strengthen economic supports	Strengthen financial security				
	Unemployment benefit programs	X			Government (local, state, Federal)
	Housing stabilization policies				
	The National Neighborhood Stabilization Program			X	Government (local, state, Federal)
Strengthen access to mental health care	Coverage of mental health conditions in health insurance policies				
	Mental Health Parity Laws	X		X	Healthcare  Government (local, state, Federal)
Establish protective environments	Means restriction				
	Intervening at hot spots	X			Government (local, state, Federal)
	Safe storage practices		X (attempts)	X (Safe storage of firearms and medication)	Government (local, state, Federal)
	Organizational policies and culture				

**Comment [A]:** I'll help you complete the lead sector column. For the other columns, you just need to insert a check-mark based on the evidence you describe in the narrative for a particular program or policy. For example, if the evidence shows impact on suicide, then put a check-mark in that column. If the study also found effects on risk or protective factors, then put a check-mark in that column as well.

		Best Available Evidence			
	<i>Together for Life</i>	X			Business/Labor
	<i>US Air Force Suicide Prevention Program</i>	X		X (family violence)	Government (local, state, Federal)  Business/Labor
	Community-based policies to reduce excessive alcohol use				
	<i>Alcohol outlet density</i>	X		X	Government (local, state, Federal)
Promote connectedness to protect against suicide	Peer norm approaches				
	<i>Sources of Strength</i>			X	Public Health Social Services
	Community-engagement activities				
	<i>Greening vacant urban spaces</i>			X	Public Health
Teach coping and problem-solving skills	Social emotional learning				
	<i>Youth Aware of Mental Health Program</i>		X		Public Health Social Services
	<i>Signs of Suicide</i>		X	X	
	<i>Good Behavior Game</i>		X	X	
	Parenting skill and family relationship approaches				
	<i>The Incredible Years</i>			X	Public Health Social Services

		Best Available Evidence			
	Strengthening Families 10-14			X	
Identify and support people at-risk	Gatekeeper training				
	Mental Health First Aid			X	Public Health Healthcare Social Services
	Screening combined with care management				
	Henry Ford Perfect Depression Care (Pre-cursor to Zero Suicide)	X		X	Healthcare
	Crisis Intervention				
	National Suicide Prevention Lifeline		X	X	Public Health Social Services
	Applied Suicide Intervention Skills Training		X	X	
Intervene to lessen harms and prevent future risk	Treatment for people at risk of suicide				
	Improving Mood – Promoting Access to Collaborative Treatment (IMPACT)		X	X	Healthcare Social Services
	Collaborative Assessment and Management of Suicidality (CAMS)		X	X	
	Dialectical Behavioral Therapy		X	X	
	Attachment-Based Family Therapy		X		
	Treatment to prevent re-attempts				

		Best Available Evidence			
	<i>ED Brief Intervention with Follow-up Visits</i>	X			Healthcare
	<i>Active follow-up contact approaches</i>	X	X		
	<i>CBT for Suicide Prevention</i>				
	Postvention				
	<i>StandBy Response Service</i>		X		Healthcare
	Safe messaging following a suicide				
	<i>Media Guidelines</i>	X			Public Health

<sup>1</sup>This column refers to the lead sectors well positioned to bring leadership and resources to implementation efforts. For each strategy, there are many other sectors such as non-governmental organizations that are instrumental to prevention planning and implementing the specific programmatic activities.

## Overview

This technical package represents a select group of strategies based on the best available evidence to help communities and states sharpen their focus on prevention activities with the greatest potential to prevent suicide. Broadly, the strategies represented include those with a focus on preventing suicide from happening in the first place as well as approaches to lessen the immediate and long-term effects of suicidal behavior for individuals, families, communities, and society. Specifically, the strategies include strengthening economic supports; strengthening access to mental health care; establishing protective environments; promoting connectedness to protect against suicide; teaching coping and problem-solving skills; identifying and supporting people at-risk; and intervening to lessen harms and prevent future risk.

This package supports the National Strategy for Suicide prevention, Goal 1, “Integrate and coordinate suicide prevention activities across multiple sectors and settings.” (p.29) It also supports the National Action Alliance for Suicide Prevention’s priority (2016) “To create and disseminate a framework for comprehensive community-based suicide prevention.”

Commitment, cooperation, and leadership from numerous sectors, including public health, education, justice, health care, social services, business/labor, and government can bring about the successful implementation of this package.

### What is a Technical Package?

A technical package is a compilation of a core set of strategies to achieve and sustain substantial reductions in a specific risk factor or outcome (Frieden, 2014). Technical packages help communities and states prioritize prevention activities based on the best available evidence. This technical package has three components. The first component is the **strategy** or the preventive direction or actions to achieve the goal of preventing suicide. The second component is the **approach**. The approach includes the specific ways to advance the strategy. This can be accomplished through *programs, policies, and practices*. The approaches included come primarily from studies based in the United States. The **evidence** for each of the approaches in preventing suicide or its associated risk factors is included as the third component. This package is intended as a resource to guide and inform prevention decision-making in communities and states.

### Preventing Suicide is a Priority

Suicide, as defined by the Centers for Disease Control and Prevention (CDC), is part of a broader class of behavior called *self-directed violence*. Self-directed violence refers to behavior directed at oneself that deliberately results in injury or the *potential* for injury (Crosby, Ortega, & Melanson, 2011). Self-directed violence may be *suicidal* or *non-suicidal* in nature. For the purposes of this document, we refer only to behavior where suicide is intended.

- **Suicide** is a death caused by self-directed injurious behavior with any intent to die as a result of the behavior.
- **Suicide attempt** is defined as a *non-fatal* self-directed and potentially injurious behavior with any intent to die as a result of the behavior. A suicide attempt may or may not result in injury.

### **Suicide is highly prevalent.**

Suicide presents a major challenge to public health in the United States and worldwide. It contributes to premature death, morbidity, lost productivity, and health care costs (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014). In 2014 in the U.S., the most recent death data available, suicide was responsible for 42,773 deaths, which is approximately one suicide every 12 minutes (Centers for Disease Control and Prevention, 2016d). In 2014, suicide ranked as the tenth leading cause of death and has been among the top twelve leading causes of death since 1975 in the U.S (Centers for Disease Control and Prevention, 2016d). Overall suicide rates have increased 24% from 1999 to 2014 (Curtin, Warner, & Hedegaard, 2016). Suicide is a problem throughout the life span; it is the second leading cause of death among those aged 10–19 years, also second among persons in their 20s and 30s; it is the fourth leading cause among persons in their 40s and seventh among persons in their 50s (Centers for Disease Control and Prevention, 2016d).

Suicides reflect only a portion of the problem (Crosby, Han, Ortega, Parks, & Gfroerer, 2011). Substantially more people are hospitalized as a result of nonfatal suicidal behaviors (i.e. suicide attempts) than are fatally injured, and an even greater number are either treated in ambulatory settings (e.g., emergency departments) or not treated at all (Crosby, Han, et al., 2011). For example, during 2014, among adults aged 18 years and older, for every one suicide there were 9 adults treated in hospital emergency departments for self-harm injuries, 27 who reported making a suicide attempt, and over 227 who reported seriously considering suicide (i.e. ideation) (Ferdon et al., In press). Suicides, suicide attempts, and ideation take an immense emotional, physical, and economic toll (see p. 9) on individuals, families and communities. By one conservative estimate, for every death by suicide six people are directly impacted (i.e. survivors). Based on this figure it is estimated that there are over 13 million survivors in the U.S. and unfortunately, survivorship itself is a risk factor for suicide (Crosby & Sacks, 2002).

### **Suicide is associated with several risk and protective factors.**

Suicide, like other human behaviors, is complex with no single determining cause. Instead, suicide occurs in response to multiple biological, psychological, interpersonal, environmental and societal influences that interact with one another, often over time. The social-ecological model is a useful framework for viewing and understanding suicide risk factors identified in the literature (Dahlber & Krug, 2002):

Some risk Factors for suicide include (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014):

- **Individual:** History of depression and other mental illnesses, alcohol and drug abuse, previous suicide attempt, violence victimization, genetic and biological determinants, hopelessness
- **Relationship:** High conflict or violent relationships, sense of isolation and lack of social support, family/loved one's history of suicide, financial and work stress
- **Community:** Inadequate community connectedness, barriers to health care (e.g., lack of access to providers and medications)
- **Societal:** Availability of lethal means of suicide, unsafe media portrayals of suicide, stigma associated with help-seeking and mental illness

It is important to recognize that the vast majority of individuals who are depressed (or who have other risk factors) do *not* die by suicide. Furthermore, the relevance of each risk factor can vary by age, race, gender, sexual orientation, residential geography, and socio-cultural and economic status (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014)

Protective factors, or those influences that guard *against* the risk for suicide, can also be found across the different levels of the social-ecological model. Protective factors identified in the literature include: effective coping and problem solving skills, moral objections to suicide, strong and supportive relationships with partners, friends, and family; connectedness to school, community and other social institutions; availability of quality and ongoing physical and mental health care, and reduced access to lethal means (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014). These protective factors can either counter a specific risk factor or guard against a number of risks associated with suicide.

### **Suicide is connected to other forms of violence.**

As indicated above, suicide is connected to other forms of violence. Suicide and other forms of violence often share some of the same root causes (Butchart, Phinney, Check, & Villaveces, 2004; Kleven, Simon, & Chen, 2012). For example, in neighborhoods where there is low social cohesion, or where residents don't support and trust each other, people are at higher risk for suicide (Desai, Dausey, &

Rosenheck, 2005) as well as perpetration of child maltreatment (Coulton, Crampton, Irwin, Spilsbury, & Korbin, 2007; Freisthler, Merritt, & LaScala, 2006), teen dating violence (Capaldi, Knoble, Shortt, & Kim, 2012), intimate partner violence (Pinchevsky & Wright, 2012), and youth violence (Sampson, Morenoff, & Gannon-Rowley, 2002). Additionally, a lack of economic opportunities and unemployment are associated with suicide (Luo, Florence, Quispe-Agnoli, Ouyang, & Crosby, 2011; Reeves et al., 2012), as well as perpetration of child maltreatment (D. Runyan, Wattam, Ikeda, Hassan, & Ramiro, 2002), intimate partner violence (Heise & Garcia-Moreno, 2002; Pinchevsky & Wright, 2012), sexual violence (Centers for Disease Control and Prevention, 2016c) and youth violence (Wilson, 2011). Other shared risk factors for suicide and violence occur at the individual level and include substance abuse, mental health problems, witnessing violence, and a lack of problem-solving skills (Centers for Disease Control and Prevention, 2016a, 2016c, 2016e; U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012).

Just as risk factors may be shared across suicide and violence, so too may protective factors overlap. For example, connectedness increases individual's and communities' resilience to suicide and other forms of violence, including connectedness to one's community (Basile, Hamburger, Swahn, & Choi, 2013; Borowsky, Hogan, & Ireland, 1997; Centers for Disease Control and Prevention, 2016b; Coulton et al., 2007; Kleiman, Riskind, Schaefer, & Weingarden, 2012; Pinchevsky & Wright, 2012; Widome, Sieving, Harpin, & Hearst, 2008), school (Basile, Espelage, Rivers, McMahon, & Simon, 2009; Capaldi et al., 2012; Carter, McGee, Taylor, & Williams, 2007; DeGue et al., 2013; Hong, Kral, Espelage, & Allen-Meares, 2012; Losel & Farrington, 2012), family (Capaldi et al., 2012; Centers for Disease Control and Prevention, 2016a; Elgar, Craig, Boyce, Morgan, & Vella-Zarb, 2009; Maimon, Browning, & Brooks-Gunn, 2010; Resnick, Ireland, & Borowsky, 2004), caring adults (Capaldi et al., 2012; Losel & Farrington, 2012; Maimon et al., 2010), and pro-social peers (Capaldi et al., 2012; Losel & Farrington, 2012).

### **The health and economic consequences of suicide are substantial.**

Suicide and suicide attempts have far-reaching consequences for individuals, families, and communities (Dunne, McIntosh, & Dunne-Maxim, 1987; Mishara, 1995; National Action Alliance for Suicide Prevention: Suicide Attempt Survivors Task Force, 2014; National Action Alliance for Suicide Prevention: Survivors of Suicide Loss Task Force, 2015). Research indicates that the health consequences of violence, including suicide, are much more extensive than injury and death. Suicide attempt survivors (i.e. those with lived experience) may suffer long-term health and mental health consequences ranging from anger, guilt, and physical impairment, depending on the means and severity of the attempt (Chapman & Dixon-Gordon, 2007). Similarly, survivors of a loved one's suicide may experience ongoing pain and suffering including complicated grief (Mitchell, Kim, Prigerson, & Mortimer-Stephens, 2004), stigma, depression, anxiety, post-traumatic stress disorder, and increased risk of suicidal ideation and suicide (Julie Cerel, McIntosh, Neimeyer, Maple, & Marshall, 2014; Sudak, Maxim, & Carpenter, 2008).

The economic toll of suicide is immense as well. The total lifetime costs associated with nonfatal injuries and deaths caused by self-directed violence in 2013 were approximately \$93.5 billion after adjusting for under-reporting of suicide (Shepard, Gurewich, Lwin, Reed, & Silverman, 2016). The overwhelming burden of these costs results from lost productivity over the life course, with the average cost per suicide being over \$1.3 million (Shepard et al., 2016).

### **Suicide can be prevented.**

Despite the myths surrounding suicide, like most public health problems, suicide is preventable (U.S. Public Health Service, 1999). And while progress will continue to be made into the future, evidence for numerous programs, practices, and policies currently exists, and many programs are ready to be implemented now. Just as suicide is not caused by a single factor, research suggests that suicide will not be prevented by any single intervention taking place in any single setting (Silverman & Maris, 1995; U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012). Rather, suicide prevention is best achieved by a focus across the individual-, relationship-, family-, community, and societal-levels and across all sectors, private and public (e.g., business, public health, physical and behavioral healthcare, justice, education, labor) (National Action Alliance for Suicide Prevention, 2014; World Health Organization, 2014). According to Frieden (2014), successful public health programs also require political commitment, funding, communication, and performance monitoring.

### **Assessing the Evidence**

This technical package includes programs, practices, and policies with evidence of impact on suicide or risk or protective factors for suicide. To be considered for inclusion in the technical package, the program, practice, or policy selected had to meet at least one of these criteria: a) meta-analyses or systematic reviews showing impact on suicide; b) evidence from at least one rigorous (e.g., randomized controlled trial [RCT] or quasi-experimental design) evaluation study that found significant preventive effects on suicide; c) meta-analyses or systematic reviews showing impact on risk or protective factors for suicide, or d) evidence from at least one rigorous (e.g., RCT or quasi-experimental design) evaluation study that found significant impacts on risk or protective factors for suicide. Finally, consideration was also given to the likelihood of achieving beneficial effects on multiple forms of violence; no evidence of harmful effects on specific outcomes or with particular subgroups; and feasibility of implementation in a U.S. context if the program, policy, or practice has been evaluated in another country.

Within this technical package, some approaches do not yet have research evidence demonstrating impact on rates of suicide but instead are supported by evidence indicating impacts on risk or protective factors for suicide (e.g., help-seeking, stigma reduction, depression, connectedness). In terms of the strength of the evidence, programs that have demonstrated effects on suicidal behavior (e.g., reductions in deaths, attempts) provide a higher-level of evidence, but the evidence base is not that strong in all areas. For instance, there has been less evaluation of community engagement and

family programs on suicidal behavior. Thus, approaches in this package that have effects on risk or protective factors reflect the developmental nature of the evidence base and the use of the best available evidence at a given time.

It is also important to note that there is often significant heterogeneity among the programs, policies, or practices that fall within one approach or strategy area in terms of the nature and quality of the available evidence. Not all programs, policies, or practices that utilize the same approach (e.g., gatekeeper training) are equally effective, and even those that are effective may not work across all populations. Tailoring programs and more evaluation may be necessary to address different population groups. The examples provided are not intended to be a comprehensive list of evidence-based programs, policies, or practices for each approach, but rather illustrate models that have been shown to impact suicide or have beneficial effects on risk or protective factors for suicide. In practice, the effectiveness of the programs, policies and practices identified in this package will be strongly dependent on the quality of their implementation and the communities in which they are implemented. Implementation guidance to assist practitioners, organizations and communities will be developed separately.

### Context and Cross-Cutting Themes

The strategies and approaches that have been included in this technical package represent different levels of the social ecology, with efforts intended to impact the community and societal levels, as well individual and relationship levels. The strategies and approaches are intended to work in combination and reinforce each other to prevent suicide (see box below). The strategies are arranged in order such that those strategies hypothesized to have the greatest potential for broad public health impact on suicide are included first, followed by those that might impact more select populations (e.g., persons who have already made a suicide attempt).

Preventing Suicide	
Strategy	Approach
Strengthen economic supports	<ul style="list-style-type: none"> <li>Strengthen financial security</li> <li>Housing stabilization policies</li> </ul>
Strengthen access to mental health care	<ul style="list-style-type: none"> <li>Coverage of mental health conditions in health insurance policies</li> </ul>
Establish protective environments	<ul style="list-style-type: none"> <li>Means restriction</li> <li>Organizational policies and culture</li> <li>Community-based policies to reduce excessive alcohol use</li> </ul>
Promote connectedness to protect against suicide	<ul style="list-style-type: none"> <li>Peer norm approaches</li> <li>Community engagement activities</li> </ul>

Teach coping and problem-solving skills	<ul style="list-style-type: none"> <li>• Social-emotional learning</li> <li>• Parenting skill and family relationship approaches</li> </ul>
Identify and support people at risk	<ul style="list-style-type: none"> <li>• Gatekeeper training</li> <li>• Screening combined with care management</li> <li>• Crisis intervention</li> </ul>
Intervene to lessen harms and prevent future risk	<ul style="list-style-type: none"> <li>• Treatment for people at-risk of suicide</li> <li>• Treatment to prevent re-attempts</li> <li>• Postvention</li> <li>• Safe messaging following a suicide</li> </ul>

The example programs, policies, and practices have been implemented within particular contexts. The social and cultural context of communities is critically important to take into account when selecting strategies and approaches. Practitioners in the field may be in the best position to assess the needs and strengths of their communities and work with community members to make decisions about the combination of approaches included here that are best suited to their context.

Suicide ideation, attempts, morbidity and mortality vary by gender, race/ethnicity, age, occupation, and other important population characteristics. Barriers to disclosure, help seeking, timely access to quality care, and ongoing support are profoundly complex and may also vary by population and community characteristics. Ideally, the availability of multiple approaches tailored to the economic, cultural, and environmental context of individuals and communities are desirable as they may increase the likelihood of removing barriers to supportive and effective care and provide opportunities to develop individual and community resilience. These culturally appropriate approaches can then be included in comprehensive strategies to maximize the public health impact on reducing suicide-related morbidity and mortality among individuals and within communities.

This package includes strategies where public health agencies are well positioned to bring leadership and resources to implementation efforts. It also includes strategies where public health can serve as an important collaborator (e.g., strategies addressing community and societal level risks), but where leadership and commitment from other sectors such as business/labor or health care is critical to implement a particular policy or program (e.g., workplace policies; screening combined with care management). The role of various sectors in the implementation of a strategy or approach in preventing suicide is described further in the section on *Sector Involvement*.

In the sections that follow, the strategies and approaches with the best available evidence for preventing suicide are described.

## Strengthen Economic Supports

### Rationale

Public health research suggests that some of the biggest impacts on health come from policies developed to improve socioeconomic conditions (Frieden, 2010). Downturns in the economy and increases in unemployment and home foreclosures are associated with increased rates of suicide (Fowler, Gladden, Vagi, Barnes, & Frazier, 2015; Luo et al., 2011). Policies that strengthen financial security and keep housing stable may help prevent suicide by reducing stress and anxiety and the potential for a crisis situation and at the same time assist people to improve their financial situations.

### Approaches

Economic and housing supports for individuals and families can be strengthened by improving policies that enhance financial security and stabilize housing for people, especially in times of economic need.

- **Strengthen household financial security.** Findings from the U.S. show that suicide rates increase during economic recessions marked by high unemployment rates, job losses, and economic instability and decrease during economic expansions and periods marked by low unemployment rates, particularly for working-age individuals 25 to 64 years old (Luo et al., 2011; Fowler et al., 2015). Policies that support financial security during difficult economic times have been shown to mitigate the risk of economic crises on suicide rates.
- **Housing stabilization policies** aim to keep people in their homes during times of financial insecurity. This may occur through programs that provide affordable housing such as through government subsidies or through other options available to potential homebuyers such as loan modification programs, move-out planning, or financial counseling services that help minimize the risk or impact of foreclosures and eviction.

### Potential Outcomes

- Reduced suicide rates
- Lower foreclosure rates
- Lower eviction rates
- Reduced emotional distress

### Evidence

There is evidence that policies that strengthen household financial security and that stabilize housing can reduce suicide risk.

- **Strengthen household financial security.** *Unemployment benefit programs* provide income protection during periods of unemployment in an effort to prevent or lessen the economic

**Comment [A]:** I think we need to describe what this approach is more specifically so that we can then show the evidence in the next section.

hardship for those experiencing job loss and enduring unemployment. An examination of variations in U.S. *unemployment benefit programs* across states demonstrated that the impact of unemployment on suicide was offset in those states that provided greater than average unemployment benefits greater (Cylus, Glymour, & Avendano, 2014). Another U.S. study examining the link between unemployment and suicide risk using monthly suicide data, length of unemployment, and job losses found that the duration of unemployment, as opposed to just the loss of job, predicted suicide risk (Classen & Dunn, 2012). Together, these results suggest that not only should state unemployment benefit programs be **generous** in their financial allocations, but also in their duration.

- **Housing stabilization policies.** *The National Neighborhood Stabilization Program* provides affordable housing options for low, moderate, and middle-income homebuyers and offers financial assistance to eligible individuals for the purchase of a new home. While it has not been rigorously evaluated for its impact on suicide outcomes, specifically, it addresses foreclosure and evictions, risk factors for suicide. A longitudinal analysis of annual data on suicides and foreclosures demonstrated that as the proportion of foreclosed properties increased in U.S. states, so did the state suicide rate, particularly among working-aged adults (Houle & Light, 2014). Another study of data from 16 U.S. states participating in the National Violent Death Reporting System found that suicides precipitated by home foreclosures and evictions increased more than 100% from 2005 (before the housing crisis began) to 2010 (after it had peaked; Fowler et al. (2015)). Most of these suicides occurred prior to the actual loss of the decedent's home. These findings suggest that integrating suicide prevention resources, messaging, and referrals into financial, foreclosure, and move-out planning and counseling services may help to prevent suicide.

**Comment [A]:** Tom had a concern about this term so we've tried to explain it above. Hopefully it's a bit clearer. The interpretation from the study isn't the easiest.

**Comment [A]:** Did the National Neighborhood Stab. Program increase housing options and decrease evictions for people who participated? I think this would be useful to say.

## Strengthen Access to Mental Health Care

### Rationale

Mental illness is a risk factor for suicide-- Studies suggest that up to 90% of people who die by suicide may have had a mental illness at the time of their deaths (Cavanagh, Carson, Sharpe, & Lawrie, 2003) and research on state-level suicide rates have been found to be correlated with general mental health measures such as depression (Arsenault-Lapierre, Kim, & Turecki, 2004). While most people with mental health problems do not attempt or die by suicide (Olfson, Gerhard, Huang, Crystal, & Stroup, 2015) and most people who have attempted suicide will not go on to die by suicide (Owens, 2002), assuring access to affordable mental health care for people in need is critical to suicide prevention.

### Approaches

A major approach to strengthening access to mental health care is through the provision of health insurance policies that include coverage for such services.

- **Coverage of mental health conditions in health insurance policies.** Historically, mental health care was viewed as separate from physical health care and many health insurance plans either did not provide coverage of mental health services or such services were available but not affordable--due to higher co-pays or co-insurance-- or set limits on the number of visits allowed. More recently, improvements have been made with many health insurance policies providing greater levels of mental health coverage and more provide coverage that is on par with coverage for other health concerns, i.e. mental health parity. These policies can help prevent suicide by increasing the accessibility and affordability, and ultimately the use of, needed mental health services. As more people access mental health services this helps normalize treatment seeking in the population, reduces symptoms of mental illnesses like depression and bipolar disorder, and in turn, reduce rates of suicide and suicide attempts.

### Potential Outcomes

- Increased utilization of mental health services
- Decreased symptoms of mental illnesses
- Decreased rates of suicide attempts
- Decreased rates of suicide

### Evidence

There is evidence suggesting that coverage of mental health conditions in health insurance policies can reduce risk factors associated with suicide and may directly impact suicide rates.

- **Coverage of mental health conditions in health insurance policies.** The National Survey of Drug Use and Health is a nationally representative survey of the U.S. population that provides

data on substance use, mental health conditions, and services utilization. Using data from this survey, Harris, Carpenter, and Bao (2006) found that 12 months after states enacted *mental health parity laws*, self-reported use of mental healthcare services significantly increased. Moreover, subsequent research by Lang (2013) examined state mental health laws and suicide rates between 1990 and 2004 and found that mental health parity laws, specifically, were associated with an approximate 5% reduction in suicide rates. This reduction, in the 29 states with parity laws, equated to the prevention of 592 suicides per year and a cost savings of \$1.3-3.1 million per suicide prevented (Lang, 2013).

## Establish Protective Environments

### Rationale

Prevention efforts that focus not only on individual behavior change (e.g., help-seeking, treatment interventions) but on changes to the environment (e.g., policy-level interventions, modifications to the environment) as well, increase the likelihood of success (Haddon, 1980). Protective environments may be defined in part, as those where risk factors associated with suicide are limited and where protective factors are encouraged. Examples of risk factors include easy access to lethal means, stigma related to help-seeking, and substance abuse (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012). Protective factors include such things as social connectedness and access to mental health services (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012). Establishing environments that address these factors where individuals live, work, and play, can help prevent suicide.

### Approaches

The current evidence suggests three promising approaches for creating environments that protect against suicide.

- **Reducing access to lethal means.** Means of suicide such as firearms, hanging/suffocation, or jumping from heights provide little opportunity for rescue and, as such, have high case fatality rates (e.g., about 85% of people who use a firearm in a suicide attempt will die from the injury). Research also indicates that 1) the interval between thinking about and attempting suicide can be as short as 5 or 10 minutes (Deisenhammer et al., 2009; Simon et al., 2001) and 2) that people tend *not* to substitute a different method when a highly lethal method is unavailable or difficult to access (Hawton, 2007; Yip et al., 2012). Therefore, increasing the time interval between the thought and the suicide attempt, for example, by making it more difficult to access lethal means, can be lifesaving. The following are examples of approaches reducing access to lethal means:
  - *Intervening at Suicide Hotspots.* Suicide hotspots, or places where suicides may take place relatively easily, include tall structures (e.g., bridges and cliffs), railway tracks, and isolated locations such as parks. Efforts to prevent suicide at these locations include erecting barriers to prevent jumping and installing signs and telephones to encourage individuals who are considering suicide, to seek help (Cox et al., 2013).
  - *Safe Storage Practices.* Safe storage of medications, firearms, and other household products can reduce the risk for suicide by separating individuals who may be vulnerable and/or impulsive from easy access to lethal means. Such practices may

include education and counseling around storing firearms--locked in a secure place (e.g., in a gun safe or lock box), preferably unloaded and separate from the ammunition--and keeping medicines in a locked cabinet or other secure location away from people who may be at risk or who have made prior attempts (Rowhani-Rahbar, Simonetti, & Rivara, 2016; C. W. Runyan et al., 2016).

- **Organizational policies and culture** that promote protective environments may be implemented in places of employment. Such policies and cultural values may promote prosocial behavior (e.g., asking for help), skill building, changing social norms, referral and access to helping services (e.g. mental health, substance abuse treatment, financial counseling), and encourage leadership support from the top down. Such policies and cultural shifts can positively impact organizational climate and morale and help prevent suicide and its related risk factors (e.g. depression, social isolation).
- **Community-based policies to reduce excessive alcohol use.** Research studies in the United States have found that greater alcohol availability is positively associated with alcohol-involved suicides (Escobedo & Ortiz, 2002; Giesbrecht et al., 2015). Policies to reduce excessive alcohol use broadly include zoning to limit alcohol outlet locations and density, taxes on alcohol, and bans on the sale of alcohol for individuals under the legal drinking age. These policies are important because acute alcohol use has been found to be associated with more than one-third of suicides and approximately 40% of suicide attempts (Cherpitel, Borges, & Wilcox, 2004).

### Potential Outcomes

- Increase in safe storage of lethal means
- Reduction in suicide attempts
- Reduction in suicide deaths
- Increase in help-seeking
- Reduction in alcohol-related suicide deaths

### Evidence

The evidence for the effectiveness of means restriction and other ways to establish protective environments is some of the strongest in the field (Zalsman et al., 2016), as described below.

- **Means restriction.** A meta-analysis examining the impact of *suicide hotspot interventions* implemented in combination or in isolation, both in the U.S. and abroad, found associated reduced rates of suicide (Cox et al., 2013; Pirkis et al., 2015). For example, after erecting a barrier on the Jacques-Cartier bridge in Canada, the suicide rate from jumping from the bridge decreased from about 10 suicide deaths per year to about 3 deaths per year (Perron, Burrows, Fournier, Perron, & Ouellet, 2013). Moreover, the reduction in suicides by jumping was

sustained even when all bridges and nearby jumping sites were considered, suggesting little to no displacement of suicides to other jumping sites (Perron et al., 2013). Further evidence for the effectiveness of bridge barriers was demonstrated by a study examining the impact of the *removal* of safety barriers from the Grafton Bridge in Auckland, New Zealand. After removal of the barrier, sadly, both the number and rate of suicide increased fivefold (Beautrais, 2001; Beautrais, Gibb, Fergusson, Horwood, & Larkin, 2009).

Another form of means reduction involves implementation of *safe storage practices*. In a case-control study of firearm-related events identified from 37 counties in Washington, Oregon, and Missouri, and from 5 trauma centers, Grossman et al. (2005) found that storing firearms unloaded, separate from ammunition, in a locked place and/or secured with a safety device was protective of suicide attempts among adolescents. Further, a recent systematic review of clinic and community-based education and counseling interventions suggested that the provision of safety devices significantly increased safe firearm storage practices compared to counseling alone or compared to the provision of economic incentives to acquire safety devices on one's own (Rowhani-Rahbar et al., 2016). Another program, *The Emergency Department Counseling on Access to Lethal Means (ED CALM)*, trained psychiatric emergency clinicians in a large children's hospital to provide lethal means counseling and safe storage boxes to parents of patients under age 18 receiving care for suicidal behavior. In a pre-post quality improvement project, Runyan et al. (2016) found that at post-test 76% (of the 55% of parents follow-up, n=114) reported that all medications in the home were locked up as compared to fewer than 10% at the time of the initial emergency department visit. Among parents who indicated the presence of guns in the home at pre-test (i.e. 67%), all (100%) reported guns were currently locked up at post-test (C. W. Runyan et al., 2016).

- **Organizational policies and culture.** *Together for Life* is a workplace program of the Montreal Police Force implemented to address suicide among officers. Policy and program components were designed to foster an organizational culture that promoted mutual support and solidarity among all members of the Force. The program included training of supervisors, managers and all units to improve competencies in identifying suicidal risk and to improve use and awareness of existing resources. The program also included an education campaign to improve awareness and help-seeking (Mishara & Martin, 2012). Police suicides were tracked over 12 years and compared to rates in the control city of Quebec. The suicide rate in the intervention group decreased significantly by 78.9% to a rate of 6.42 suicides per 100,000 population per year compared to an 11% increase in the control city (rate: 29.0 per 100,000) (Mishara & Martin, 2012).

Another example of this approach is the *United States Air Force Suicide Prevention Program (AFSPP)*. AFSPP included 11 policy and education initiatives and was designed to change the

culture of the Air Force surrounding suicide. The program uses leaders as role models and agents of change, establishes expectations for behavior related to awareness of suicide risk, develops population skills and knowledge (i.e., education and training), and investigates every suicide (i.e., outcomes measurement). The program represents a fundamental shift from viewing suicide and mental illness solely as medical problem and instead sees them as larger service-wide problems impacting the whole community (K. L. Knox, Litts, Talcott, Feig, & Caine, 2003). Using a time-series design to examine the impact of the AFSPP program on various violence-related outcomes, researchers found that the program was associated with a 33% relative risk reduction in suicide (K. L. Knox et al., 2003). The program was also associated with relative risk reductions in related outcomes including moderate and severe family violence (30% and 54%, respectively), homicide (51%), and accidental death (18%) (K. L. Knox et al., 2003). A longitudinal assessment of the program over the period 1981 to 2008 (16 years before the 1997 launch of the program and 11 years post-launch) found significantly lower rates of suicide after the program was launched than before (K. L. Knox et al., 2010). These effects were sustained over time, except in 2004, which the authors found was associated with less rigorous implementation in that year than in the other years (K. L. Knox et al., 2010).

- **Community-based policies to reduce excessive alcohol use.** While multiple policies to limit alcohol use exist, several studies on alcohol outlet *density*, specifically, suggest that measures to reduce alcohol outlet density can potentially reduce alcohol-involved suicides. Additionally, a longitudinal analysis of alcohol outlet density, suicide mortality, and hospitalizations for suicide attempts over 6 years in 581 California zip codes indicated that the density of bars, specifically, is related to suicide and suicide attempts, particularly in rural areas (Johnson, Gruenewald, & Remer, 2009).

## Promote Connectedness to Protect Against Suicide

### Rationale

Sociologist, Emile Durkheim theorized in 1897 that weak social bonds, i.e. lack of connectedness, are among the chief causes for suicidality (Durkheim, 1951). *Connectedness* is the degree to which an individual or group of individuals are socially close, interrelated, or share resources with others (Centers for Disease Control and Prevention, 2009). Social connections can be formed within and between multiple levels of the social ecology (Dahlber & Krug, 2002), for instance between individuals (e.g. peers, neighbors, co-workers), families, schools, neighborhoods, workplace, faith communities, cultural groups, and society as a whole. Related to connectedness, *social capital* refers to a sense of trust in one's community and neighborhood, social integration, and also the availability and participation in social organizations (Beyer, Layde, Hamberger, & Laud, 2015; Muennig, Cohen, Palmer, & Zhu, 2013). Many ecological cross-sectional and longitudinal studies have examined the impact of aspects of social capital on depression symptoms, depressive disorder, mental health more generally, and suicide. While the evidence is still being built the pattern is towards an inverse association between social capital measured by social trust, community/ neighborhood engagement, and improved mental health. Connectedness and social capital together can serve to protect against suicidal behaviors by decreasing isolation, encouraging adaptive coping behaviors, increasing belongingness, personal value and worth all of which helps individuals to build resilience in the face of adversity. Connectedness can also provide individuals with better access to formal supports and resources, mobilize communities to meet the needs of its members and provide collective primary prevention activities to the community as a whole (Centers for Disease Control and Prevention, 2009)

### Approaches

Promoting connectedness among individuals and within communities through modeling peer norms and enhancing community engagement can protect against suicide.

- **Peer norm approaches** seek to normalize prosocial behaviors/protective factors for suicide such as help-seeking, reaching out and talking to trusted adults, and peer connectedness. These approaches typically target youth and are delivered in school settings but can also be implemented in community settings.

- **Community engagement activities.** Community engagement is an aspect of social capital. Community engagement approaches may involve residents participating in a range of activities, including religious activities, community clean-up and greening activities, and physical exercise. These activities provide opportunities for residents to become more involved in the community and to connect with other community members, organizations, and resources, resulting in enhanced overall physical health, reduced stress, and decreased depressive symptoms, thereby reducing risk of suicide.

### Potential Outcomes

- Reduction in maladaptive coping attitudes and behaviors
- Increase in healthy coping attitudes and behaviors
- Increase in referrals for youth in distressed
- Increase help-seeking behaviors
- Positive perception of adult support

### Evidence

Current evidence suggests that peer norm approaches and community engagement can reduce risk factors associated with suicidal behaviors.

- **Peer norm approaches.** Evaluations show that programs such as *Sources of Strength* can improve school norms and beliefs about suicide that are created and disseminated by student peers. In a randomized controlled trial of *Sources of Strength* conducted with 18 high-schools (6 metropolitan, 12 rural), Wyman et al. (2010) found that the program improved peer leaders' adaptive norms regarding suicide, their connectedness to adults, and school engagement. Peer leaders were also more likely than controls to refer a suicidal friend to an adult. Among students, the intervention increased perceptions of adult support for suicidal youths and the acceptability of seeking help. Perception of adult support increased most in students with a history of suicidal ideation. Finally, trained peer leaders also reported a greater decrease in maladaptive coping attitudes compared with untrained leaders (Wyman et al., 2010).
- **Community engagement activities.** A vacant lot greening initiative was undertaken in Philadelphia between 1999 and 2008. Local residents and community members worked together to green 4,436 lots (or 7.8 million square feet) in 4 areas of the city. Researchers found significant associated reductions in community residents' self-reported stress levels and engagement in more physical exercise than residents in control vacant lot areas. Other benefits included reductions in firearm assaults and vandalism (Branas et al., 2011).

**Comment [A]:** Linda, I still might like to research this approach a bit more to find a more robust study.

## Teach Coping and Problem-Solving Skills

### Rationale

Building life skills prepares individuals to successfully tackle every day challenges and adapt to stress and adversity. Life skills encompasses many concepts, but most often include coping and problem-solving skills, conflict resolution, and critical thinking. Life skills are important in shielding individuals from suicidal behaviors (World Health Organization, 2014). Suicide prevention programs that focus on life and social skills training are drawn from social cognitive theories (Bandura, 1986), surmising that individuals who engage in suicidal behavior is attributed to either direct learning, modeling, and environmental and individual (e.g. hopelessness) characteristics. The literature linking life skills and suicide is robust--- The inability to employ adequate coping strategies to cope with immediate stressors or identify and find solutions for problems have been characterized among suicide attempters (Pollock & Williams, 2004). Treatments that include bolstering problem skills (Goldsmith, Pellmar, Kleinman, & Bunney, 2002) and include problem-solving techniques (Ghahramanlou-Holloway, Bhar, Brown, Olsen, & Beck, 2012; Townsend et al., 2001) appear to reduce suicidal ideation and attempts more effectively. Prevention programs focused on teaching these skills target youth, parents and families and have been used with both universal and at-risk populations. While many do not target suicidal behaviors directly, these programs strive to train youth and parents important life skills to offset the underlying vulnerabilities that contribute to engaging in high risk behaviors early in life.

### Approaches

Current evidence provides support for the following two approaches:

- **Social emotional learning programs** focus on developing and strengthening communication and problem-solving skills, emotion regulation, conflict resolution, help seeking and coping skills. These approaches address a range of risk and protective factors for suicidal behavior. They provide children and youth with skills to resolve problems in relationships, school, and with peers, and help youth to address other negative influences (e.g., substance use) associated with suicide. These approaches are typically delivered to all students in a particular grade or school, although some programs also focus on groups of students considered to be at high-risk for suicide. Opportunities to practice and reinforce skills are an important part of programs that work (Herman, Borden, Reinke, & Webster-Stratton, 2011).
- **Parenting skill and family relationship programs** are designed to strengthen parenting skills, enhance positive parent-child interactions, and improve children's behavioral and emotional skills and abilities. Several parenting and family relationship programs have been shown in rigorous evaluations to improve resilience and reduce risk factors for various behaviors,

including ones closely related to suicide, such as depression, internalizing behaviors, and substance abuse (M. S. Knox, Burkhart, & Hunter, 2010).

### Potential Outcomes

- Reduction in suicide attempts and suicide ideation
- Enhanced knowledge of risk and protective factors associated with suicide
- Reduction in suicide risk behaviors (i.e., depression, anxiety, conduct problems, substance abuse)
- Improve and normalize help-seeking behavior
- Enhance social competence and emotional regulation skills
- Enhance problem-solving and conflict management skills

### Evidence

There are several programs with evidence that supports teaching social, emotional and parenting skills to reduce suicidal behaviors and associated risk factors.

- **Social emotional learning programs.** In a cluster-randomized controlled trial of **YAM** conducted across 10 European Union countries and 168 schools, students participating in the **YAM** program were significantly less likely to have an incident suicide attempt (OR 0.45, 95%CI 0.24–0.85;  $p=0.014$ ) and severe suicidal ideation (0.50, 0.27-0.92;  $p=0.025$ ) at the 12-month follow-up compared to the control group. Additionally, related to severe suicide ideation, in the **YAM** group absolute risk fell by 0.50% and RR fell by 49.6% (Wasserman et al., 2014).

Additionally, in a randomized controlled trial, **SOS** was shown to reduce self-reported suicide attempts at 3-months post intervention among participating students compared to control students. The **SOS** program also increased students' knowledge of how to get help for themselves or friends for depression and/or suicidal thoughts, and favorable attitudes toward help-seeking. **SOS** participants with a lifetime history of suicide attempt were also less likely to report planning a suicide in the 3 months following the program compared to lower-risk participants (Schilling, Aseltine, & James, 2016).

Finally, in an outcome evaluation of the **GBG**, first graders assigned to **GBG** reported half the adjusted odds of suicidal ideation and suicide attempts. The beneficial effect of the program was consistent for suicidal ideation regardless of whether baseline covariates were included. The **GBG** effect on attempts was less robust in some adjusted models including caregiver mental health. In the second cohort of **GBG** students, neither suicidal ideation nor suicide attempts were significantly different between **GBG** and the control interventions

Comment [A]: Kristin, can you add what the acronym stands for and a sentence or two about the program?

Comment [A]: Same comment as above.

Comment [A]: Same comment.

(Wilcox et al., 2008). This finding likely arose due to the lack of implementation fidelity and pointed to the need for *GBG* to be delivered with precision, consistency, and teacher support. *GBG* was also found to be associated with reduced risk of later substance abuse, a risk factor for suicide (Kellam et al., 2008).

- **Parenting skill and family relationship programs.** Parenting and family skills training approaches have shown promising impacts in preventing key risk factors associated with suicide. Several studies have demonstrated the effect of *The Incredible Years* program on reducing internalizing symptoms, such as anxiety and depression, and child conduct problems (C. H. Webster-Stratton, Reid, & Beauchaine, 2011; Webster-Stratton, Jamila Reid, & Stoolmiller, 2008). The program is also associated with improved problem-solving and conflict management; these skills were maintained at 1-year follow-up (Reid, Webster-Stratton, & Hammond, 2003; C. Webster-Stratton & Hammond, 1997; C. Webster-Stratton, Reid, & Hammond, 2001). The program demonstrated greater benefits as the dosage of the intervention increased (Herman et al., 2011).

Additionally, *Strengthening Families* has been shown to decrease externalizing behaviors, alcohol use, and drug use among youth participants and reductions in depression, alcohol use, and drug use among participating families (Spath, Gyll, & Day, 2002).

Comment [A]: Sentence or two about the program is needed here.

Comment [A]: Same comment.

## Identify and Support People At-Risk

### Rationale

In order to decrease suicide, attention to people at increased or high risk is necessary as these individuals tend to experience suicidal behavior at higher than average rates. These vulnerable or disadvantaged populations include, but are not limited to, individuals with lower socio-economic status or who are living with a mental health problem; people who have attempted suicide previously, individuals who are institutionalized, have been victims of violence, or are homeless; and members of certain ethnic minority groups. Supporting these vulnerable groups requires proactive case finding along with access to, and retention in, mental health services. Finding effective ways of identifying at-risk or vulnerable groups, customizing services to make them accessible and maintaining care remain key challenges. For example, simply improving services does not guarantee that those services will be used by those most in need of them, nor will it necessarily increase the number of people who follow treatments that are recommended. People who are disadvantaged face social and economic issues that may adversely affect their ability to respond to the treatments or advice that are offered.

### Approaches

The following three approaches focus on identifying and supporting people at increased risk.

- **Gatekeeper training** is designed to train teachers, coaches, providers and others in the community to identify people who may be at risk of suicide and to respond effectively, including facilitating treatment seeking and support services. Gatekeeper training is typically implemented in schools to identify at-risk youth and within health care settings to identify adults (and youth).
- **Screening combined with care management and overall continuity of care** has been used in primary care and behavioral health care settings to assure that people who may be at high-risk of suicide are identified and receive ongoing treatment as needed, particularly after inpatient discharge and other transitions within the healthcare system so they don't 'slip through the cracks'. These approaches typically employ screening for depression and/or suicide combined with collaborative treatment planning between patients and their providers and patient follow-up.
- **Crisis intervention.** These approaches provide support and referral services, typically by connecting a person in crisis (or a friend or family member of someone at-risk) to trained volunteers and/or professional staff via telephone hotline, online chat, or text messaging. Crisis intervention approaches are intended to impact key risk factors for suicide, including feelings of

depression, hopelessness, and subsequent mental health care utilization. Like means reduction, crisis interventions can put space or time between an individual who may be considering suicide and harmful behavior.

### Potential Outcomes

- Reduction in suicide attempts
- Reduction in suicide deaths
- Increased identification of individuals at-risk for suicidal behavior
- Increased at-risk individuals in treatment
- Increased community members trained to identify at-risk individuals
- Increased referrals for health care

### Evidence

There is evidence that community gatekeeper programs are successful in reducing suicides and suicide attempts but the efforts must be maintained (Substance Abuse and Mental Health Services Administration, Center for Mental Health Services. Report to Congress: Garret Lee Smith Suicide Prevention Program. US Department of Health and Human Services: Rockville, MD, 2014). However, there is limited evidence for effectiveness screening programs, but at the same time, standard principles for public health screening make them promising (Pena & Caine, 2006). The number of studies evaluating crisis intervention services is limited, but a few studies do indicate that those who use the hotline services have decreased suicidal thoughts and behavior.

- **Gatekeeper training.** In a randomized controlled trial of 300 participants of *Mental Health First Aid (MHFA)*, the intervention group reported greater confidence in providing help to others, greater likelihood of advising people to seek professional help, improved concordance with health professionals about treatments, and decreased stigmatizing attitudes. Additionally, the intervention resulted in improved mental health of the participants themselves. All results were statistically significant at  $p < .05$ . (Kitchener & Jorm, 2004). Additional research rigorously evaluating *MHFA* for its impact on the first aid recipients themselves and suicidal behavior is needed (Kitchener & Jorm, 2006).
- **Screening combined with care management and overall continuity of care.** An examination of the impact of the *Henry Ford Perfect Depression Care (Pre-cursor to Zero Suicide)* program found that there was a dramatic and statistically significant decrease in the rate of suicide between the baseline years prior to the intervention (1999 and 2000) to the intervention years (2002-2009). During this time period, the suicide rate fell 82% (C. E. Coffey, 2006; C. E. Coffey,

**Comment [A]:** Kristin can you do me a favor and create an endnote reference for this in the endnote library called (Suicide.enl) and then insert the ref here? Thank you!

**Comment [A]:** Please add a sentence describing MHFA

**Comment [A]:** Please add sentence here describing the program.

Coffey, & Ahmedani, 2013). Further, suicide rates also declined among HMO members who participated in targeted suicide prevention efforts and received mental health specialty services. However, for those HMO members who accessed only general medical services as opposed to specialty mental health services, the suicide rate increased (M. Coffey, Coffey, & Ahmedani, 2015).

- **Crisis intervention.** In an evaluation of the effectiveness of the National Suicide Prevention Lifeline (NSPL) to prevent suicide, 1,085 suicidal individuals who called the hotline completed a standard risk assessment for suicide, and 380 of those completed a follow-up assessment between 1 and 52 days after the initial assessment. Researchers found that over half of the initial sample were seriously considering suicide when they called, and they had a plan for their suicide. Researchers also found that participants experienced significant decreases in suicidality over the course of the telephone session, and that levels of hopelessness and psychological pain continued to decrease after their initial call (Gould, Kalafat, Harrismunfakh, & Kleinman, 2007).

In another study, this time employing a randomized controlled trial, Gould, Cross, Pisani, Munfakh, and Kleinman (2013) assessed the impact of the *Applied Suicide Intervention Skills Training (ASIST)*, a widely implemented gatekeeper training program, across the NSPL network of hotlines over the period 2008-2009. Using data from 1,410 suicidal individuals who called 17 Lifeline centers, researchers found that compared to callers who spoke to counselors that received the usual care training, individuals who spoke with counselors trained in ASIST were significantly more likely to feel less depressed, less suicidal, less overwhelmed, and more hopeful by the end of their call to the hotline. Counselors trained in ASIST were also more skilled at keeping callers on the phone longer and establishing a connection with them. However, training in ASIST did not result in more comprehensive suicide risk assessments than usual care training (Gould et al., 2013).

Comment [A]: Maybe add a detail here about ASIST

## Intervene to Lessen Harms and Prevent Future Risk

### Rationale

Individuals who have experienced mental health challenges, suicidal ideation, and/or who have made suicide attempts and/or have engaged in non-suicidal self-injury are at increased risk of suicide (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012). Risk of suicide can also increase among those who have lost a friend, family member, co-worker, or other acquaintance to suicide (Pitman, Osborn, King, & Erlangsen, 2014). Exposure to sensationalized or uninformed reporting regarding on suicide may heighten the risk of suicide among vulnerable individuals and can inadvertently contribute to suicide contagion (Etzersdorfer & Sonneck, 1998; Niederkrotenthaler & Sonneck, 2007).

### Approaches

A broad array of approaches to lessen harms and reduce future risk of suicide among those at increased risk include the provision of mental health care and improved continuity of care, improving linkage to care through active post-discharge planning and follow-up that decreases barriers to ongoing therapeutic support, increasing connectedness to supportive others, addressing bereavement, and framing communications to emphasize resilience, decrease negative affect, and to prevent contagion.

- **Treatment for people at-risk of suicide** typically includes various forms of psychotherapy delivered by licensed providers to help individuals with mental health problems and other risk factors for suicide with problem-solving, impulsivity and emotion regulation.
- **Treatment to prevent re-attempts.** These approaches typically include follow-up contact and use diverse modalities (e.g., home visits, mail, telephone, e-mail) to engage recent suicide attempt survivors in continued treatment to prevent re-attempts. Treatment may focus on improved coping skills, mindfulness, and other emotional regulation skills, and may include case management home visits to increase adherence to treatment and continuity of care; and one-on-one interpersonal therapy and/or group therapy. Approaches that engage and connect attempters to peers and providers are especially important because many attempters do not present to aftercare; 12%-25% reattempt within a year, and 3%-9% of attempt survivors die by suicide within 1 to 5 years of their initial attempt (Inagaki et al., 2015)
- **Postvention** approaches are implemented *after* a suicide has taken place and may include debriefing sessions, counseling, and/or bereavement support groups for surviving friends and family members/loved ones. These programs have not typically been evaluated for their impact on suicide or suicidal behavior but may reduce survivors' guilt, feelings of depression, and complicated grief (Szumilas & Kutcher, 2011).

- **Safe messaging following a suicide.** The manner in which information on a recent suicide is communicated to the public (e.g. school assemblies, mass media, social media) can heighten the risk of suicide among vulnerable individuals and can inadvertently contribute to suicide contagion. Therefore, responsible and safe reporting may help prevent suicide and/or suicide contagion.

### Potential Outcomes

- Reduction in mental health-related sequelae
- Increase connectedness
- Improved coping skills
- Improved messaging following suicide
- Reduction in re-attempts

### Evidence

The evidence addressing strategies to lessen harm and prevent future risk of suicide includes the evaluation of effects of specific approaches on risk and protective factors as well as suicide-related mortality. However, because the evaluation of suicide-related mortality requires large sample sizes and extended follow-up, much of the evidence in this area primarily focuses on risk and protective factors.

- **Treatment for people at-risk of suicide.**

**Improving Mood – Promoting Access to Collaborative Treatment (IMPACT)** has been shown to significantly improve quality of life, and to reduce functional impairment, depression and suicidal ideation over 24-months of follow-up (Hunkeler et al., 2006; Unutzer et al., 2006) relative to patients who received care as usual.

**Collaborative Assessment and Management of Suicidality (CAMS)** has been tested and supported in 6 correlational studies (Jobes, 2012), in a variety of inpatient and outpatient settings and in one RCT with several additional RCTs under way. CAMS has been associated with significant improvements in suicidal ideation, overall symptom distress, and feelings of hopelessness at 12 month follow-up among a community-based sample of suicidal outpatients. (Comtois et al., 2011).

**Dialectical Behavioral Therapy.** In a randomized controlled trial of women with recent suicidal or self-injurious behavior, those receiving DBT were half as likely to make a suicide attempt at

**Comment [A]:** Need sentences for the rest of the programs. Ugh. Sorry.

two-year follow-up than women receiving community treatment (23% vs 46%), required less hospitalization for suicide ideation, and had lower medical risk across all suicide attempts and self-injurious acts combined (Linehan et al., 2006).

**Attachment-Based Family Therapy (ABFT).** A randomized controlled trial of ABFT (Diamond et al., 2010) found that suicidal adolescents assigned to ABFT experienced significantly greater improvement in suicidal ideation over 24 weeks of follow-up than did adolescents assigned to enhanced usual care (-4.37 vs. -2.34;  $p = .001$ ;  $d=0.97$ ). Additionally, a higher percentage of ABFT participants reported no suicidal ideation in the week prior to assessment at 12 weeks than did adolescents receiving enhanced usual care (69.2% vs. 34.6%;  $p = .01$ ; OR= 4.25) and at 24 weeks (82.1% vs. 46.2%;  $p = .006$ ; OR=5.37) (Diamond et al., 2010).

- **Treatment to prevent re-attempts.**

**Emergency Department Brief Intervention with Follow-up Visits.** A randomized controlled trial that enrolled suicide attempters from eight hospital emergency departments in five culturally different sites found that a brief intervention combined with 9 follow-up visits over 18-months was associated with significantly fewer deaths from suicide relative to a treatment-as-usual group (0.2% versus 2.2%, respectively;  $\chi^2 = 13.83$ ,  $P < 0.001$ ) (Fleischmann et al., 2008).

**Active follow-up contact approaches** intended to prevent reattempts among patients that have been hospitalized and subsequently discharged for suicide attempts have been found in a meta-analysis conducted by Inagaki et al. (2015) to reduce reattempts by approximately 17% for up to 12 months post-discharge, however, the long-term effects of these approaches on reattempts has not yet been demonstrated. Also, because the number of trials and associated sample sizes included in this meta-analysis were small, it was not possible to determine the effect of active contact and follow-up approaches on death by suicide. In a randomized controlled trial of postcrisis suicide prevention long-term follow-up contact approach, Motto and Bostrom (2001) found that patients who refused ongoing care but who were randomized to be contacted by letter four times per year had a lower rate of suicide over two years of follow-up than did patients in the control group who received no further contact. Other studies have also shown post-crisis letters and coping cards to be protective against suicide ideation and attempts (Hassanian-Moghaddam, Sarjani, Kolahi, & Carter, 2011; Wang et al., 2016).

- **Postvention.** In a study by Visser, Comans, and Scuffham (2014), *StandBy* clients were significantly less likely to be at high risk for suicidality than a suicide bereaved comparison group who had not had contact with the *StandBy* program (48% and 64% respectively,  $p = 0.005$ ). Additionally, research suggests that active postvention approaches in which outreach to

suicide survivors occurs at the scene of a suicide is associated with intake into treatment sooner, greater attendance at support group meetings, and attendance at more meetings compared to passive postvention (versus passive approaches where survivors self-refer for services) (J. Cerel & Campbell, 2008).

**Safe messaging following a suicide.** The most compelling evidence supporting the effect of *media guidelines* on reduction in suicides comes from Austria. After a sharp increase in suicides on the Viennese subway, media guidelines were introduced and an interrupted time series design was used to evaluate the national impact of the guidelines on subsequent suicides. Changes in the quality and quantity of media reporting resulted in a reduction of 81 suicides annually (95% confidence interval: -149 to -13;  $t = -2.32$ ,  $df = 54$ ,  $p < 0.024$ ) in the Viennese subway system (Niederkrötenenthaler & Sonneck, 2007)

## Sector Involvement

Public health can play an important and unique role in addressing suicide. Public health agencies, which typically place prevention at the forefront of efforts and work to create broad population-level impact, can bring critical leadership and resources to bear on this problem. For example, these agencies can serve as a convener, bringing together partners and stakeholders to plan, prioritize, and coordinate suicide prevention efforts. Public health agencies are also well positioned to collect and disseminate data, implement preventive measures, evaluate programs, and track progress. Although public health can play a leadership role in preventing suicide, the strategies and approaches outlined in this technical package cannot be accomplished by the public health sector alone.

Other sectors vital to implementing this package include, but are not limited to, education, government (local, state, and federal), social services, health services, business/labor, justice, housing, media, and organizations that comprise the civil society sector such as faith-based organizations, youth-serving organizations, foundations, and other non-governmental organizations. Collectively, these sectors can make a difference in preventing suicide by impacting the various contexts and underlying risks that contribute to suicide.

The strategies and approaches described in this technical package are summarized in Appendix A along with the relevant sectors that are well positioned to lead implementation efforts.

[I can write the text specific to the strategies and approaches. I've done this for the other TPs and am happy to do the same here. This is the section where we distinguish the strategies where public health is best positioned to lead from those where leadership is necessary from other sectors and how public health can assist, etc.]

Regardless of strategy, action by many sectors will be necessary for the successful implementation of this package. In this regard, all sectors can play an important and influential role in creating safe and protective environments where individuals who are at high risk of suicide can easily access the mental healthcare and services they need.

## Monitoring and Evaluation

Monitoring and evaluation are necessary components of the public health approach to prevention. It is important to have timely and reliable data to monitor the extent of the problem and to evaluate the impact of prevention efforts. Data are necessary for program implementation; planning, implementation, and assessment all rely on accurate measurement of the problem.

Surveillance data helps researchers and practitioners track changes in the burden of suicide. Surveillance systems exist at the federal, state, and local levels. It is important to assess the availability of surveillance data and data systems across these levels to identify and address gaps in the systems. CDC's National Vital Statistics System and the National Violent Death Reporting System (NVDRS) are examples of surveillance systems that provide data on deaths from suicide. NVDRS, for example, is a state-based surveillance system that combines data from death certificates, law enforcement reports, and coroner or medical examiner reports to provide detailed information on the circumstances of violent deaths, including suicide, which can assist communities in guiding prevention approaches (Blair, Fowler, Jack, & Crosby, 2016). The National Electronic Injury Surveillance System-All Injury Program (NEISS-AIP) provides nationally representative data about all types and causes of nonfatal injuries treated in U.S. hospital emergency departments, and can be used to assess national rates of, and trends in, self-harm injuries by cause (e.g., falls, poisoning, etc.), age, race/ethnicity, sex, disposition (where the injured person goes when released from the Emergency Department (<http://www.cdc.gov/injury/wisqars/nonfatal.html>)).

In addition to information on deaths and nonfatal injuries, there are also surveillance systems that provide national, state, and some local estimates of suicidal behavior. The Youth Risk Behavior Surveillance System (YRBSS) collects information from a nationally representative sample of 9-12 grade students and is a key resource in monitoring health-risk behaviors among youth, including whether youth have seriously considered attempting suicide, attempted suicide, made a plan, or required treatment by a doctor or nurse for a suicide attempt that resulted in an injury, poisoning, or overdose (Brener et al., 2013). The YRBSS data are obtained from a national school-based survey conducted by CDC as well as school-based state, territorial, tribal, and large urban school district survey conducted by education and health agencies. The National Survey on Drug Use and Health (NSDUH) is an annual nationwide survey of individuals aged 12 years and older that provides national and state-level estimates of drug use and mental health-related issues, including suicide ideation and suicide attempts (<https://nsduhweb.rti.org/respweb/homepage.cfm>).

It is also important at all levels (local, state, and federal) to address gaps in responses, track progress of prevention efforts and evaluate the impact of those efforts, including the impact of this technical package. Evaluation data, produced through program implementation and monitoring, is essential to provide information on what does and does not work to reduce rates of suicide and its associated risk

and protective factors. Theories of change and logic models that identify short, intermediate, and long-term outcomes are an important part of program evaluation.

The evidence-base for suicide prevention has advanced greatly over the last few decades. However, additional research is needed to understand the impact of prevention programs on preventing suicide, as opposed to merely examining the effectiveness of programs to impact risk factors associated with suicide. More research is also needed to examine the effectiveness of upstream and community-level strategies to prevent suicide at the population level. Lastly, it will be important for researchers to test the effectiveness of combinations of the strategies and approaches included in this package. Most existing evaluations focus on approaches implemented in isolation. However, there is potential to understand the synergistic effects within a comprehensive prevention approach. Additional research is needed to understand the extent to which combinations of strategies and approaches result in greater reductions in suicide than individual programs, practices, or policies.

## Conclusion

## References

(See last 7 pages after Appendix—EndNote put them there because it thought the Appendix/table was part of the regular text; Didn't want to cut and paste table for fear it'd get de-formatted)

## Appendix A: Summary of Strategies and Approaches to Prevent Suicide

Strategy	Approach/Program, Practice or Policy	Best Available Evidence			Lead Sectors <sup>1</sup>
		Suicide	Suicide Attempts or Ideation	Other Risk/Protective Factors for Suicide	
Strengthen economic supports	Strengthen financial security				
	Unemployment benefit programs	X			Government (local, state, Federal)
	Housing stabilization policies				
	The National Neighborhood Stabilization Program			X	Government (local, state, Federal)
Strengthen access to mental health care	Coverage of mental health conditions in health insurance policies				
	Mental Health Parity Laws	X		X	Healthcare  Government (local, state, Federal)
Establish protective environments	Means restriction				
	Intervening at hot spots	X			Government (local, state, Federal)
	Safe storage practices		X (attempts)	X (Safe storage of firearms and medication)	Government (local, state, Federal)
	Organizational policies and culture				

**Comment [A]:** I'll help you complete the lead sector column. For the other columns, you just need to insert a check-mark based on the evidence you describe in the narrative for a particular program or policy. For example, if the evidence shows impact on suicide, then put a check-mark in that column. If the study also found effects on risk or protective factors, then put a check-mark in that column as well.

		Best Available Evidence			
	<i>Together for Life</i>	X			Business/Labor
	<i>US Air Force Suicide Prevention Program</i>	X		X (family violence)	Government (local, state, Federal)  Business/Labor
	Community-based policies to reduce excessive alcohol use				
	<i>Alcohol outlet density</i>	X		X	Government (local, state, Federal)
Promote connectedness to protect against suicide	Peer norm approaches				
	<i>Sources of Strength</i>			X	Public Health Social Services
	Community-engagement activities				
	<i>Greening vacant urban spaces</i>			X	Public Health
Teach coping and problem-solving skills	Social emotional learning				
	<i>Youth Aware of Mental Health Program</i>		X		Public Health Social Services
	<i>Signs of Suicide</i>		X	X	
	<i>Good Behavior Game</i>		X	X	
	Parenting skill and family relationship approaches				
	<i>The Incredible Years</i>			X	Public Health Social Services

		Best Available Evidence			
	Strengthening Families 10-14			X	
Identify and support people at-risk	Gatekeeper training				
	Mental Health First Aid			X	Public Health Healthcare Social Services
	Screening combined with care management				
	Henry Ford Perfect Depression Care (Pre-cursor to Zero Suicide)	X		X	Healthcare
	Crisis Intervention				
	National Suicide Prevention Lifeline		X	X	Public Health Social Services
	Applied Suicide Intervention Skills Training		X	X	
Intervene to lessen harms and prevent future risk	Treatment for people at risk of suicide				
	Improving Mood – Promoting Access to Collaborative Treatment (IMPACT)		X	X	Healthcare Social Services
	Collaborative Assessment and Management of Suicidality (CAMS)		X	X	
	Dialectical Behavioral Therapy		X	X	
	Attachment-Based Family Therapy		X		
	Treatment to prevent re-attempts				

		Best Available Evidence			
	<i>ED Brief Intervention with Follow-up Visits</i>	X			Healthcare
	<i>Active follow-up contact approaches</i>	X	X		
	<i>CBT for Suicide Prevention</i>				
	Postvention				
	<i>StandBy Response Service</i>		X		Healthcare
	Safe messaging following a suicide				
	<i>Media Guidelines</i>	X			Public Health

<sup>1</sup>This column refers to the lead sectors well positioned to bring leadership and resources to implementation efforts. For each strategy, there are many other sectors such as non-governmental organizations that are instrumental to prevention planning and implementing the specific programmatic activities.

## Overview

This technical package represents a select group of strategies based on the best available evidence to help communities and states sharpen their focus on prevention activities with the greatest potential to prevent suicide. These strategies include strengthening economic supports; strengthening access to mental health care; creating protective environments; promoting connectedness to protect against suicide; teaching coping and problem-solving skills; identifying and supporting people at-risk; and intervening to lessen harms and prevent future risk. The strategies represented in this package include those with a focus on preventing suicide from happening in the first place as well as approaches to lessen the immediate and long-term harms of suicidal behavior for individuals, families, communities, and society. The strategies in the technical package support the goals and objectives of the National Suicide Prevention Strategy and the National Action Alliance for Suicide Prevention's priority to strengthen community-based prevention. Commitment, cooperation, and leadership from numerous sectors, including public health, education, justice, health care, social services, business/labor, and government can bring about the successful implementation of this package.

### What is a Technical Package?

A technical package is a compilation of a core set of strategies to achieve and sustain substantial reductions in a specific risk factor or outcome (Frieden, 2014). Technical packages help communities and states prioritize prevention activities based on the best available evidence. This technical package has three components. The first component is the **strategy** or the preventive direction or actions to achieve the goal of preventing suicide. The second component is the **approach**. The approach includes the specific ways to advance the strategy. This can be accomplished through *programs, policies, and practices*. The approaches included come primarily from studies based in the United States. The **evidence** for each of the approaches in preventing suicide or its associated risk factors is included as the third component. This package is intended as a resource to guide and inform prevention decision-making in communities and states.

### Preventing Suicide is a Priority

Suicide, as defined by the Centers for Disease Control and Prevention (CDC), is part of a broader class of behavior called *self-directed violence*. Self-directed violence refers to behavior directed at oneself that deliberately results in injury or the *potential* for injury (Crosby, Ortega, & Melanson, 2011). Self-directed violence may be *suicidal* or *non-suicidal* in nature. For the purposes of this document, we refer only to behavior where suicide is intended:

- **Suicide** is a death caused by self-directed injurious behavior with any intent to die as a result of the behavior.

- **Suicide attempt** is defined as a *non-fatal* self-directed and potentially injurious behavior with any intent to die as a result of the behavior. A suicide attempt may or may not result in injury.

**Suicide is highly prevalent.** Suicide presents a major challenge to public health in the United States and worldwide. It contributes to premature death, morbidity, lost productivity, and health care costs (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014). In 2014 (the most recent year of available death data), suicide was responsible for 42,773 deaths in the U.S., which is approximately one suicide every 12 minutes (Centers for Disease Control and Prevention, 2016d). In 2014, suicide ranked as the 10th leading cause of death and has been among the top 12 leading causes of death since 1975 in the U.S (Centers for Disease Control and Prevention, 2016d). Overall suicide rates have increased 24% from 1999 to 2014 (Curtin, Warner, & Hedegaard, 2016). Suicide is a problem throughout the life span; it is the second leading cause of death among those aged 10–19 years, also second among persons in their 20s and 30s; it is the fourth leading cause among persons in their 40s and seventh among persons in their 50s (Centers for Disease Control and Prevention, 2016d).

Suicides reflect only a portion of the problem (Crosby, Han, Ortega, Parks, & Gfroerer, 2011). Substantially more people are hospitalized as a result of nonfatal suicidal behavior (i.e. suicide attempts) than are fatally injured, and an even greater number are either treated in ambulatory settings (e.g., emergency departments) or not treated at all (Crosby, Han, et al., 2011). For example, during 2014, among adults aged 18 years and older, for every one suicide there were 9 adults treated in hospital emergency departments for self-harm injuries, 27 who reported making a suicide attempt, and over 227 who reported seriously considering suicide (i.e. ideation) (Ferdon et al., In press).

**Suicide is associated with several risk and protective factors.** Suicide, like other human behaviors, is complex with no single determining cause. Instead, suicide occurs in response to multiple biological, psychological, interpersonal, environmental and societal influences that interact with one another, often over time. The social-ecological model is a useful framework for viewing and understanding suicide risk factors identified in the literature (Dahlberg & Krug, 2002):

Some risk Factors for suicide include (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014):

- **Individual:** History of depression and other mental illnesses, alcohol and drug abuse, previous suicide attempt, violence victimization, genetic and biological determinants, hopelessness
- **Relationship:** High conflict or violent relationships, sense of isolation and lack of social support, family/loved one's history of suicide, financial and work stress
- **Community:** Inadequate community connectedness, barriers to health care (e.g., lack of access to providers and medications)
- **Societal:** Availability of lethal means of suicide, unsafe media portrayals of suicide, stigma associated with help-seeking and mental illness

**Comment [A]:** Need to drop the figure and write the factors up in narrative form.

It is important to recognize that the vast majority of individuals who are depressed (or who have other risk factors) do *not* die by suicide. Furthermore, the relevance of each risk factor can vary by age, race, gender, sexual orientation, residential geography, and socio-cultural and economic status (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014)

Protective factors, or those influences that guard *against* the risk for suicide, can also be found across the different levels of the social-ecological model. Protective factors identified in the literature include: effective coping and problem solving skills, moral objections to suicide, strong and supportive relationships with partners, friends, and family; connectedness to school, community and other social institutions; availability of quality and ongoing physical and mental health care, and reduced access to lethal means (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014). These protective factors can either counter a specific risk factor or guard against a number of risks associated with suicide.

**Suicide is connected to other forms of violence.** Suicide and other forms of violence often share some of the same root causes (Butchart, Phinney, Check, & Villaveces, 2004; Kleven, Simon, & Chen, 2012). For example, in neighborhoods where there is low social cohesion, or where residents don't support and trust each other, people are at higher risk for suicide (Desai, Dausey, & Rosenheck, 2005) as well as perpetration of child maltreatment (Coulton, Crampton, Irwin, Spilsbury, & Korbin, 2007; Freisthler, Merritt, & LaScala, 2006), teen dating violence (Capaldi, Noble, Shortt, & Kim, 2012), intimate partner violence (Pinchevsky & Wright, 2012), and youth violence (Sampson, Morenoff, & Gannon-Rowley, 2002). Additionally, a lack of economic opportunities and unemployment are associated with suicide (Luo, Florence, Quispe-Agnoli, Ouyang, & Crosby, 2011; Reeves et al., 2012), as well as perpetration of child maltreatment (D. Runyan, Wattam, Ikeda, Hassan, & Ramiro, 2002), intimate partner violence (Heise & Garcia-Moreno, 2002; Pinchevsky & Wright, 2012), sexual violence (Centers for Disease Control and Prevention, 2016c) and youth violence (Wilson, 2011). Other shared risk factors for suicide and violence occur at the individual level and include substance abuse, mental health problems, witnessing violence, and a lack of problem-solving skills (Centers for Disease Control and Prevention, 2016a, 2016c, 2016e; U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012).

Just as risk factors may be shared across suicide and violence, so too may protective factors overlap. For example, connectedness increases individual's and communities' resilience to suicide and other forms of violence, including connectedness to one's community (Basile, Hamburger, Swahn, & Choi, 2013; Borowsky, Hogan, & Ireland, 1997; Centers for Disease Control and Prevention, 2016b; Coulton et al., 2007; Kleiman, Riskind, Schaefer, & Weingarden, 2012; Pinchevsky & Wright, 2012; Widome, Sieving, Harpin, & Hearst, 2008), school (Basile, Espelage, Rivers, McMahon, & Simon, 2009; Capaldi et al., 2012; Carter, McGee, Taylor, & Williams, 2007; DeGue et al., 2013; Hong, Kral, Espelage, & Allen-Meares, 2012; Losel & Farrington, 2012), family (Capaldi et al., 2012; Centers for Disease Control and Prevention, 2016a; Elgar, Craig, Boyce, Morgan, & Vella-Zarb, 2009; Maimon, Browning, & Brooks-Gunn, 2010; Resnick, Ireland, & Borowsky, 2004), caring adults (Capaldi et al., 2012; Losel & Farrington, 2012; Maimon et al., 2010), and pro-social peers (Capaldi et al., 2012; Losel & Farrington, 2012).

**The health and economic consequences of suicide are substantial.** Suicide and suicide attempts have far-reaching consequences for individuals, families, and communities (Dunne, McIntosh, & Dunne-Maxim, 1987; Mishara, 1995; National Action Alliance for Suicide Prevention: Suicide Attempt Survivors Task Force, 2014; National Action Alliance for Suicide Prevention: Survivors of Suicide Loss Task Force, 2015). By one conservative estimate, for every death by suicide six people are directly impacted (i.e. survivors). Based on this figure it is estimated that there are over 13 million survivors in the U.S. and unfortunately, survivorship itself is a risk factor for suicide (Crosby & Sacks, 2002). Research indicates that the health consequences of violence, including suicide, are also much more extensive than injury and death. Suicide attempt survivors (i.e. those with lived experience) may suffer long-term health and mental health consequences ranging from anger, guilt, and physical impairment, depending on the means and severity of the attempt (Chapman & Dixon-Gordon, 2007). Similarly, survivors of a loved one's suicide may experience ongoing pain and suffering including complicated grief (Mitchell, Kim, Prigerson, & Mortimer-Stephens, 2004), stigma, depression, anxiety, post-traumatic stress disorder, and increased risk of suicidal ideation and suicide (Julie Cerel, McIntosh, Neimeyer, Maple, & Marshall, 2014; Sudak, Maxim, & Carpenter, 2008).

The economic toll of suicide is immense as well. The total lifetime costs associated with nonfatal injuries and deaths caused by self-directed violence in 2013 were approximately \$93.5 billion after adjusting for under-reporting of suicide (Shepard, Gurewich, Lwin, Reed, & Silverman, 2016). The overwhelming burden of these costs results from lost productivity over the life course, with the average cost per suicide being over \$1.3 million (Shepard et al., 2016).

**Suicide can be prevented.** Despite the myths surrounding suicide, like most public health problems, suicide is preventable (U.S. Public Health Service, 1999). And while progress will continue to be made into the future, evidence for numerous programs, practices, and policies currently exists, and many programs are ready to be implemented now. Just as suicide is not caused by a single factor, research

suggests that suicide will not be prevented by any single intervention taking place in any single setting (Silverman & Maris, 1995; U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012). Rather, suicide prevention is best achieved by a focus across the individual-, relationship-, family-, community, and societal-levels and across all sectors, private and public (e.g., business, public health, physical and behavioral healthcare, justice, education, labor) (National Action Alliance for Suicide Prevention, 2014; World Health Organization, 2014).

## Assessing the Evidence

This technical package includes programs, practices, and policies with evidence of impact on suicide or risk or protective factors for suicide. To be considered for inclusion in the technical package, the program, practice, or policy selected had to meet at least one of these criteria: a) meta-analyses or systematic reviews showing impact on suicide; b) evidence from at least one rigorous (e.g., randomized controlled trial [RCT] or quasi-experimental design) evaluation study that found significant preventive effects on suicide; c) meta-analyses or systematic reviews showing impact on risk or protective factors for suicide, or d) evidence from at least one rigorous (e.g., RCT or quasi-experimental design) evaluation study that found significant impacts on risk or protective factors for suicide. Finally, consideration was also given to the likelihood of achieving beneficial effects on multiple forms of violence; no evidence of harmful effects on specific outcomes or with particular subgroups; and feasibility of implementation in a U.S. context if the program, policy, or practice has been evaluated in another country.

Within this technical package, some approaches do not yet have research evidence demonstrating impact on rates of suicide but instead are supported by evidence indicating impacts on risk or protective factors for suicide (e.g., help-seeking, stigma reduction, depression, connectedness). In terms of the strength of the evidence, programs that have demonstrated effects on suicidal behavior (e.g., reductions in deaths, attempts) provide a higher-level of evidence, but the evidence base is not that strong in all areas. For instance, there has been less evaluation of community engagement and family programs on suicidal behavior. Thus, approaches in this package that have effects on risk or protective factors reflect the developmental nature of the evidence base and the use of the best available evidence at a given time.

It is also important to note that there is often significant heterogeneity among the programs, policies, or practices that fall within one approach or strategy area in terms of the nature and quality of the available evidence. Not all programs, policies, or practices that utilize the same approach (e.g., gatekeeper training) are equally effective, and even those that are effective may not work across all populations. Tailoring programs and more evaluation may be necessary to address different population groups. The examples provided are not intended to be a comprehensive list of evidence-based programs, policies, or practices for each approach, but rather illustrate models that have been shown to impact suicide or have beneficial effects on risk or protective factors for suicide. In practice, the effectiveness of the programs, policies and practices identified in this package will be strongly dependent on the quality of their

implementation and the communities in which they are implemented. Implementation guidance to assist practitioners, organizations and communities will be developed separately.

### Context and Cross-Cutting Themes

The strategies and approaches that have been included in this technical package represent different levels of the social ecology, with efforts intended to impact the community and societal levels, as well individual and relationship levels. The strategies and approaches are intended to work in combination and reinforce each other to prevent suicide (see box below). The strategies are arranged in order such that those strategies hypothesized to have the greatest potential for broad public health impact on suicide are included first, followed by those that might impact more select populations (e.g., persons who have already made a suicide attempt).

Preventing Suicide	
Strategy	Approach
Strengthen economic supports	<ul style="list-style-type: none"> <li>Strengthen household financial security</li> <li>Housing stabilization policies</li> </ul>
Strengthen access to mental health care	<ul style="list-style-type: none"> <li>Coverage of mental health conditions in health insurance policies</li> </ul>
Create protective environments	<ul style="list-style-type: none"> <li>Reducing access to lethal means among persons at-risk of suicide</li> <li>Organizational policies and culture</li> <li>Community-based policies to reduce excessive alcohol use</li> </ul>
Promote connectedness to protect against suicide	<ul style="list-style-type: none"> <li>Peer norm approaches</li> <li>Community engagement activities</li> </ul>
Teach coping and problem-solving skills	<ul style="list-style-type: none"> <li>Social-emotional learning</li> <li>Parenting skill and family relationship approaches</li> </ul>
Identify and support people at risk	<ul style="list-style-type: none"> <li>Gatekeeper training</li> <li>Screening combined with care management</li> <li>Crisis intervention</li> </ul>
Intervene to lessen harms and prevent future risk	<ul style="list-style-type: none"> <li>Treatment for people at-risk of suicide</li> <li>Treatment to prevent re-attempts</li> <li>Postvention</li> <li>Safe messaging following a suicide</li> </ul>

The example programs, policies, and practices have been implemented within particular contexts. The social and cultural context of communities is critically important to take into account when selecting strategies and approaches. Practitioners in the field may be in the best position to assess the needs and

strengths of their communities and work with community members to make decisions about the combination of approaches included here that are best suited to their context.

Suicide ideation, attempts, morbidity and mortality vary by gender, race/ethnicity, age, occupation, and other important population characteristics. Barriers to disclosure, help seeking, timely access to quality care, and ongoing support are profoundly complex and may also vary by population and community characteristics. Ideally, the availability of multiple approaches tailored to the economic, cultural, and environmental context of individuals and communities are desirable as they may increase the likelihood of removing barriers to supportive and effective care and provide opportunities to develop individual and community resilience. These culturally appropriate approaches can then be included in comprehensive strategies to maximize the public health impact on reducing suicide-related morbidity and mortality among individuals and within communities.

This package includes strategies where public health agencies are well positioned to bring leadership and resources to implementation efforts. It also includes strategies where public health can serve as an important collaborator (e.g., strategies addressing community and societal level risks), but where leadership and commitment from other sectors such as business/labor or health care is critical to implement a particular policy or program (e.g., workplace policies; screening combined with care management). The role of various sectors in the implementation of a strategy or approach in preventing suicide is described further in the section on *Sector Involvement*.

In the sections that follow, the strategies and approaches with the best available evidence for preventing suicide are described.

## Strengthen Economic Supports

### Rationale

Public health research suggests that some of the biggest impacts on health come from policies developed to improve socioeconomic conditions (Frieden, 2010). Downturns in the economy and increases in unemployment and home foreclosures are associated with increased rates of suicide (Fowler, Gladden, Vagi, Barnes, & Frazier, 2015; Luo et al., 2011). Policies that strengthen economic supports can help people stay in their homes, pay for necessities such as food and medical care, and get job training, among other things. In providing this support, stress and anxiety and the potential for a crisis situation may be reduced, thereby preventing suicide.

### Approaches

Economic and housing supports for individuals and families can be strengthened by improving policies that enhance financial security and stabilize housing for people, especially in times of economic need.

- **Strengthen household financial security.** Studies from the U.S. indicate that suicide rates increase during economic recessions marked by high unemployment rates, job losses, and economic instability and decrease during economic expansions and periods marked by low unemployment rates, particularly for working-age individuals 25 to 64 years old (Luo et al., 2011; Fowler et al., 2015).

### Potential Outcomes

- Reduced suicide rates
- Lower foreclosure rates
- Lower eviction rates
- Reduced emotional distress

### Evidence

There is evidence suggesting that strengthening household financial security and stabilizing housing can reduce suicide risk.

- **Strengthen household financial security.** An examination of variations in U.S. *unemployment benefit programs* across states demonstrated that the impact of unemployment on suicide was offset in those states that provided greater than average unemployment benefits (Cylus, Glymour, & Avendano, 2014). Another U.S. study examining the link between unemployment and suicide risk using monthly suicide data, length of unemployment, and job losses found that the duration of unemployment, as opposed to just the loss of job, predicted suicide risk (Classen & Dunn, 2012). Together, these results suggest that not only should state unemployment benefit programs be generous in their financial allocations, but also in their duration. Other measures to

**Comment [A]:** The rationale should focus on the strategy – strengthening economic supports – and how and why that might be beneficial in reducing suicide. As part of the rationale you can talk about how suicide relates to economic factors (e.g., historical data shows that suicide rates rise during periods of economic recessions and decreases during periods of economic expansion); how economic stressors (job loss, long periods of unemployment, reduced income, difficulty covering medical, food, housing expenses, etc.) increase risk for suicide and how buffering these risks can potentially protect against suicide. You cover this a

**Comment [A]:** Statement should be more along the lines of:

“There are a number of approaches that can help strengthen economic supports and buffer against the risk for suicide.”

Or

“Economic supports for individuals and families can be strengthened by targeting household financial security and ensuring stability in housing during periods of economic stress.”

**Comment [A]:** This would be a good introductory sentence to the rationale. For the two approaches, suggest saying something along the following lines:

**Strengthening household financial security** can reduce the risk for suicide by providing individuals with the necessary means to cover basic expenses and lessen the stress and hardship associated with a job loss or other unanticipated financial problems. The provision of unemployment benefits, livable wages, Temporary Assistance to Needy Families (TANF), medical benefits, and retirement and disability insurance to help cover the costs of basic necessities or to offset costs

strengthen household financial security (e.g., transfer payments related to retirement and disability insurance, unemployment insurance compensation, medical benefits, and other forms of family assistance) have also shown an impact on suicide. A study by Flavin and Radcliff (2009) examined the impact of states' per capita spending on transfer payments, medical benefits, and family assistance and total state spending on suicide rates between 1990-2000, controlling for a number of suicide risk factors (e.g., residential mobility, divorce rate, unemployment rate) at the state level. As per capita spending on total transfer payments, medical benefits, and family assistance increased there was an associated decrease in state suicide rates. Moreover, it wasn't spending in general that was associated with the reduction but spending on these types of assistance. In terms of lives saved, Flavin & Radcliff calculated the cost of reducing a state's suicide rate by a full point for the years studied. At the national level, an estimated 3,000 fewer suicides would occur per year nationwide if every state increased their per capita spending on these types of assistance by \$45 per year (Flavin & Radcliff, 2009).

- **Housing stabilization policies.** The *National Neighborhood Stabilization Program* was designed to help neighborhoods suffering from high rates of foreclosure and abandonment by slowing the deterioration of the neighborhoods and providing affordable housing options for low, moderate, and middle-income homebuyers. This program also offers financial assistance to eligible individuals for the purchase of a new home. Although this program has not been rigorously evaluated for its impact on suicide outcomes, it addresses foreclosure and eviction, which are risk factors for suicide. A longitudinal analysis of annual data on suicides and foreclosures demonstrated that as the proportion of foreclosed properties increased in U.S. states, so did the state suicide rate, particularly among working-aged adults (Houle & Light, 2014). Another study of data from 16 U.S. states participating in the National Violent Death Reporting System found that suicides precipitated by home foreclosures and evictions increased more than 100% from 2005 (before the housing crisis began) to 2010 (after it had peaked; Fowler et al. 2015). Most of these suicides occurred prior to the actual loss of the decedent's home. These findings suggest that integrating suicide prevention resources, messaging, and referrals into financial, foreclosure, and move-out planning and counseling services may help to prevent suicide.

## Strengthen Access to Mental Health Care

### Rationale

While most people with mental health problems do not attempt or die by suicide (Olfson, Gerhard, Huang, Crystal, & Stroup, 2015), previous research indicates that mental illness is an important risk factor for suicide (WHO, 2014). Studies suggest that up to 90% of people who die by suicide may have had a mental illness at the time of their deaths (Cavanagh, Carson, Sharpe, & Lawrie, 2003). State-level suicide rates have also been found to be correlated with general mental health measures such as depression (Arsenault-Lapierre, Kim, & Turecki, 2004). Findings from the National Comorbidity Survey indicate that relatively few people in the U.S. with mental health disorders receive treatment for those conditions (Kessler et al., 2005). Lack of access to mental health care is one of the contributing factors related to the underuse of mental health services (Cunningham, 2009). Identifying ways to improve access to timely, affordable, and quality mental health care for people in need is a critical component to suicide prevention (WHO, 2014). Apart from the treatment benefits, it can also serve to normalize help-seeking behavior and increase the use of such services.

### Approaches

One approach to strengthening access to mental health care is through the provision of mental health coverage in health insurance policies.

- **Coverage of mental health conditions in health insurance policies.** Federal and state laws include provisions for equal coverage of mental health services in health insurance plans that is on par with coverage for other health concerns (i.e., mental health parity). Benefits and services covered include such things as the number of visits, co-pays, deductibles, inpatient/outpatient services, prescription drugs, and hospitalizations. If a state has a stronger mental health parity law than the federal parity law, then insurance plans regulated by the state must follow the state parity law. Federal parity replaces the state law only in cases where the state law prevents the application of the federal parity law (e.g., includes coverage for some mental health conditions but not others). Equal coverage does not necessarily imply good coverage as health insurance plans vary in the extent to which benefits and services are offered to address various health conditions. Rather it helps to ensure that mental health services are covered on par with other health concerns.

### Potential Outcomes

- Increased utilization of mental health services
- Decreased symptoms of mental illnesses
- Decreased rates of suicide attempts
- Decreased rates of suicide

**Comment [A]:** Add more citations here. You could also add a sentence indicating that suicide risk varies by type of disorder and the presence of other co-morbidities such as alcohol use disorders – see pg 40 in the World Suicide Report 2014

## Evidence

There is evidence suggesting that coverage of mental health conditions in health insurance policies can reduce risk factors associated with suicide and may directly impact suicide rates.

- **Coverage of mental health conditions in health insurance policies.** The National Survey of Drug Use and Health is a nationally representative survey of the U.S. population that provides data on substance use, mental health conditions, and services utilization. Using data from this survey, Harris, Carpenter, and Bao (2006) found that 12 months after states enacted *mental health parity laws*, self-reported use of mental healthcare services significantly increased. Moreover, subsequent research by Lang (2013) examined state mental health laws and suicide rates between 1990 and 2004 and found that mental health parity laws, specifically, were associated with an approximate 5% reduction in suicide rates. This reduction, in the 29 states with parity laws, equated to the prevention of 592 suicides per year and a cost savings of \$1.3-3.1 million per suicide prevented (Lang, 2013).

## Create Protective Environments

### Rationale

Prevention efforts that focus not only on individual behavior change (e.g., help-seeking, treatment interventions) but on changes to the environment can increase the likelihood of positive behavioral and health outcomes (Haddon, 1980). Creating environments that address risk and protective factors where individuals live, work, and play, can help prevent suicide. Such approaches can involve changes to organizational climates, policy changes, and changes to the physical and social environment to reduce risk characteristics, encourage help-seeking and increase other protective factors. Modifying characteristics of the environment helps to create a context that promotes positive behavior and limits harmful behavior.

**Comment [A]:** I edited the text in the rationale to more closely align with the notion of creating a protective environment. More could probably be added in terms of the research, but this gives you a sense of what the rationale for this section might look like.

### Approaches

The current evidence suggests three promising approaches for creating environments that protect against suicide.

- **Reducing access to lethal means among persons at-risk of suicide.** Means of suicide such as firearms, hanging/suffocation, or jumping from heights provide little opportunity for rescue and, as such, have high case fatality rates (e.g., about 85% of people who use a firearm in a suicide attempt will die from the injury). Research also indicates that 1) the interval between thinking about and attempting suicide can be as short as 5 or 10 minutes (Deisenhammer et al., 2009; Simon et al., 2001) and 2) that people tend *not* to substitute a different method when a highly lethal method is unavailable or difficult to access (Hawton, 2007; Yip et al., 2012). Therefore, increasing the time interval between the thought and the suicide attempt, for example, by making it more difficult to access lethal means, can be lifesaving. The following are examples of approaches reducing access to lethal means for persons at-risk of suicide:
  - *Intervening at Suicide Hotspots.* Suicide hotspots, or places where suicides may take place relatively easily, include tall structures (e.g., bridges and cliffs), railway tracks, and isolated locations such as parks. Efforts to prevent suicide at these locations include erecting barriers to prevent jumping and installing signs and telephones to encourage individuals who are considering suicide, to seek help (Cox et al., 2013).
  - *Safe Storage Practices.* Safe storage of medications, firearms, and other household products can reduce the risk for suicide by separating individuals who may be vulnerable and/or impulsive from easy access to lethal means. Such practices may include education and counseling around storing firearms--locked in a secure place (e.g., in a gun safe or lock box), unloaded and separate from the ammunition--and keeping medicines in a

locked cabinet or other secure location away from people who may be at risk or who have made prior attempts (Rowhani-Rahbar, Simonetti, & Rivara, 2016; C. W. Runyan et al., 2016).

- **Organizational policies and culture** that promote protective environments may be implemented in places of employment. Such policies and cultural values may promote prosocial behavior (e.g., asking for help), skill building, changing social norms, referral and access to helping services (e.g. mental health, substance abuse treatment, financial counseling), and encourage leadership support from the top down. Such policies and cultural shifts can positively impact organizational climate and morale and help prevent suicide and its related risk factors (e.g. depression, social isolation).
- **Community-based policies to reduce excessive alcohol use.** Research studies in the United States have found that greater alcohol availability is positively associated with alcohol-involved suicides (Escobedo & Ortiz, 2002; Giesbrecht et al., 2015). Policies to reduce excessive alcohol use broadly include zoning to limit alcohol outlet locations and density, taxes on alcohol, and bans on the sale of alcohol for individuals under the legal drinking age. These policies are important because acute alcohol use has been found to be associated with more than one-third of suicides and approximately 40% of suicide attempts (Cherpitel, Borges, & Wilcox, 2004).

### Potential Outcomes

- Increase in safe storage of means
- Reduction in suicide attempts
- Reduction in suicide deaths
- Increase in help-seeking
- Reduction in alcohol-related suicide deaths

### Evidence

The evidence for the effectiveness of means restriction and other ways to establish protective environments is some of the strongest in the field (Zalsman et al., 2016), as described below.

- **Reducing access to lethal means among persons at-risk of suicide.** A meta-analysis examining the impact of *suicide hotspot interventions* implemented in combination or in isolation, both in the U.S. and abroad, found associated reduced rates of suicide (Cox et al., 2013; Pirkis et al., 2015). For example, after erecting a barrier on the Jacques-Cartier bridge in Canada, the suicide rate from jumping from the bridge decreased from about 10 suicide deaths per year to about 3 deaths per year (Perron, Burrows, Fournier, Perron, & Ouellet, 2013). Moreover, the reduction in suicides by jumping was sustained even when all bridges and nearby jumping sites were considered, suggesting little to no displacement of suicides to other jumping sites (Perron et al.,

2013). Further evidence for the effectiveness of bridge barriers was demonstrated by a study examining the impact of the *removal* of safety barriers from the Grafton Bridge in Auckland, New Zealand. After removal of the barrier, sadly, both the number and rate of suicide increased fivefold (Beautrais, 2001; Beautrais, Gibb, Fergusson, Horwood, & Larkin, 2009).

Another form of means reduction involves implementation of *safe storage practices*. In a case-control study of firearm-related events identified from 37 counties in Washington, Oregon, and Missouri, and from 5 trauma centers, Grossman et al. (2005) found that storing firearms unloaded, separate from ammunition, in a locked place and/or secured with a safety device was protective of suicide attempts among adolescents. Further, a recent systematic review of clinic and community-based education and counseling interventions suggested that the provision of safety devices significantly increased safe firearm storage practices compared to counseling alone or compared to the provision of economic incentives to acquire safety devices on one's own (Rowhani-Rahbar et al., 2016).

Another program, *The Emergency Department Counseling on Access to Lethal Means (ED CALM)*, trained psychiatric emergency clinicians in a large children's hospital to provide lethal means counseling and safe storage boxes to parents of patients under age 18 receiving care for suicidal behavior. In a pre-post quality improvement project, Runyan et al. (2016) found that at post-test 76% (of the 55% of parents followed up, n=114) reported that all medications in the home were locked up as compared to fewer than 10% at the time of the initial emergency department visit. Among parents who indicated the presence of guns in the home at pre-test (i.e. 67%), all (100%) reported guns were currently locked up at post-test (C. W. Runyan et al., 2016).

- **Organizational policies and culture.** *Together for Life* is a workplace program of the Montreal Police Force implemented to address suicide among officers. Policy and program components were designed to foster an organizational culture that promoted mutual support and solidarity among all members of the Force. The program included training of supervisors, managers and all units to improve competencies in identifying suicidal risk and to improve use and awareness of existing resources. The program also included an education campaign to improve awareness and help-seeking (Mishara & Martin, 2012). Police suicides were tracked over 12 years and compared to rates in the control city of Quebec. The suicide rate in the intervention group decreased significantly by 78.9% to a rate of 6.42 suicides per 100,000 population per year compared to an 11% increase in the control city (rate: 29.0 per 100,000) (Mishara & Martin, 2012).

Another example of this approach is the *United States Air Force Suicide Prevention Program (AFSPP)*. AFSPP included 11 policy and education initiatives and was designed to change the culture of the Air Force surrounding suicide. The program uses leaders as role models and agents

of change, establishes expectations for behavior related to awareness of suicide risk, develops population skills and knowledge (i.e., education and training), and investigates every suicide (i.e., outcomes measurement). The program represents a fundamental shift from viewing suicide and mental illness solely as medical problem and instead sees them as larger service-wide problems impacting the whole community (K. L. Knox, Litts, Talcott, Feig, & Caine, 2003). Using a time-series design to examine the impact of the AFSPP program on various violence-related outcomes, researchers found that the program was associated with a 33% relative risk reduction in suicide (K. L. Knox et al., 2003). The program was also associated with relative risk reductions in related outcomes including moderate and severe family violence (30% and 54%, respectively), homicide (51%), and accidental death (18%) (K. L. Knox et al., 2003). A longitudinal assessment of the program over the period 1981 to 2008 (16 years before the 1997 launch of the program and 11 years post-launch) found significantly lower rates of suicide after the program was launched than before (K. L. Knox et al., 2010). These effects were sustained over time, except in 2004, which the authors found was associated with less rigorous implementation in that year than in the other years (K. L. Knox et al., 2010).

- **Community-based policies to reduce excessive alcohol use.** While multiple policies to limit alcohol use exist, several studies on alcohol outlet *density*, specifically, suggest that measures to reduce alcohol outlet density can potentially reduce alcohol-involved suicides. Additionally, a longitudinal analysis of alcohol outlet density, suicide mortality, and hospitalizations for suicide attempts over 6 years in 581 California zip codes indicated that the density of bars, specifically, is related to suicide and suicide attempts, particularly in rural areas (Johnson, Gruenewald, & Remer, 2009).

## Promote Connectedness to Protect Against Suicide

### Rationale

Sociologist, Emile Durkheim theorized in 1897 that weak social bonds, i.e. lack of connectedness, are among the chief causes for suicidality (Durkheim, 1897/1951). *Connectedness* is the degree to which an individual or group of individuals are socially close, interrelated, or share resources with others (Centers for Disease Control and Prevention, 2009). Social connections can be formed within and between multiple levels of the social ecology (Dahlberg & Krug, 2002), for instance between individuals (e.g. peers, neighbors, co-workers), families, schools, neighborhoods, workplace, faith communities, cultural groups, and society as a whole. Related to connectedness, *social capital* refers to a sense of trust in one's community and neighborhood, social integration, and also the availability and participation in social organizations (Beyer, Layde, Hamberger, & Laud, 2015; Muennig, Cohen, Palmer, & Zhu, 2013). Many ecological cross-sectional and longitudinal studies have examined the impact of aspects of social capital on depression symptoms, depressive disorder, mental health more generally, and suicide. While the evidence is still being built the pattern is towards an inverse association between social capital measured by social trust, community/ neighborhood engagement, and improved mental health. Connectedness and social capital together can serve to protect against suicidal behaviors by decreasing isolation, encouraging adaptive coping behaviors, increasing belongingness, personal value and worth all of which helps individuals to build resilience in the face of adversity. Connectedness can also provide individuals with better access to formal supports and resources, mobilize communities to meet the needs of its members and provide collective primary prevention activities to the community as a whole (Centers for Disease Control and Prevention, 2009).

### Approaches

Promoting connectedness among individuals and within communities through modeling peer norms and enhancing community engagement can protect against suicide.

- **Peer norm approaches** seek to normalize prosocial behaviors/protective factors for suicide such as help-seeking, reaching out and talking to trusted adults, and peer connectedness. These approaches typically target youth and are delivered in school settings but can also be implemented in community settings.

- **Community engagement activities.** Community engagement is an aspect of social capital. Community engagement approaches may involve residents participating in a range of activities, including religious activities, community clean-up and greening activities, and physical exercise. These activities provide opportunities for residents to become more involved in the community and to connect with other community members, organizations, and resources, resulting in enhanced overall physical health, reduced stress, and decreased depressive symptoms, thereby reducing risk of suicide.

### Potential Outcomes

- Reduction in maladaptive coping attitudes and behaviors
- Increase in healthy coping attitudes and behaviors
- Increase in referrals for youth in distressed
- Increase help-seeking behaviors
- Positive perception of adult support

### Evidence

Current evidence suggests that peer norm approaches and community engagement can reduce risk factors associated with suicidal behaviors.

- **Peer norm approaches.** Evaluations show that programs such as *Sources of Strength* can improve school norms and beliefs about suicide that are created and disseminated by student peers. In a randomized controlled trial of *Sources of Strength* conducted with 18 high-schools (6 metropolitan, 12 rural), Wyman et al. (2010) found that the program improved peer leaders' adaptive norms regarding suicide, their connectedness to adults, and school engagement. Peer leaders were also more likely than controls to refer a suicidal friend to an adult. Among students, the intervention increased perceptions of adult support for suicidal youths and the acceptability of seeking help. Perception of adult support increased most in students with a history of suicidal ideation. Finally, trained peer leaders also reported a greater decrease in maladaptive coping attitudes compared with untrained leaders (Wyman et al., 2010).
- **Community engagement activities.** A vacant lot greening initiative was undertaken in Philadelphia between 1999 and 2008. Local residents and community members worked together to green 4,436 lots (or 7.8 million square feet) in 4 areas of the city. Researchers found significant associated reductions in community residents' self-reported stress levels and engagement in more physical exercise than residents in control vacant lot areas. Other benefits included reductions in firearm assaults and vandalism (Branas et al., 2011).

## Teach Coping and Problem-Solving Skills

### Rationale

Building life skills prepares individuals to successfully tackle every day challenges and adapt to stress and adversity. Life skills encompasses many concepts, but most often include coping and problem-solving skills, conflict resolution, and critical thinking. Life skills are important in shielding individuals from suicidal behaviors (World Health Organization, 2014). Suicide prevention programs that focus on life and social skills training are drawn from social cognitive theories (Bandura, 1986), surmising that individuals who engage in suicidal behavior is attributed to either direct learning, modeling, and environmental and individual (e.g. hopelessness) characteristics. The literature linking life skills and suicide is robust--- The inability to employ adequate coping strategies to cope with immediate stressors or identify and find solutions for problems have been characterized among suicide attempters (Pollock & Williams, 2004). Treatments that include bolstering problem skills (Goldsmith, Pellmar, Kleinman, & Bunney, 2002) and include problem-solving techniques (Ghahramanlou-Holloway, Bhar, Brown, Olsen, & Beck, 2012; Townsend et al., 2001) appear to reduce suicidal ideation and attempts more effectively. Prevention programs focused on teaching these skills target youth, parents and families and have been used with both universal and at-risk populations. While many do not target suicidal behaviors directly, these programs strive to train youth and parents important life skills to offset the underlying vulnerabilities that contribute to engaging in high risk behaviors early in life.

### Approaches

Current evidence provides support for the following two approaches:

- **Social emotional learning programs** focus on developing and strengthening communication and problem-solving skills, emotion regulation, conflict resolution, help seeking and coping skills. These approaches address a range of risk and protective factors for suicidal behavior. They provide children and youth with skills to resolve problems in relationships, school, and with peers, and help youth to address other negative influences (e.g., substance use) associated with suicide. These approaches are typically delivered to all students in a particular grade or school, although some programs also focus on groups of students considered to be at high-risk for suicide. Opportunities to practice and reinforce skills are an important part of programs that work (Herman, Borden, Reinke, & Webster-Stratton, 2011).
- **Parenting skill and family relationship programs** are designed to strengthen parenting skills, enhance positive parent-child interactions, and improve children's behavioral and emotional skills and abilities. Several parenting and family relationship programs have been shown in rigorous evaluations to improve resilience and reduce risk factors for various behaviors, including

ones closely related to suicide, such as depression, internalizing behaviors, and substance abuse (M. S. Knox, Burkhart, & Hunter, 2010).

### Potential Outcomes

- Reduction in suicide attempts and suicide ideation
- Enhanced knowledge of risk and protective factors associated with suicide
- Reduction in suicide risk behaviors (i.e., depression, anxiety, conduct problems, substance abuse)
- Improve and normalize help-seeking behavior
- Enhance social competence and emotional regulation skills
- Enhance problem-solving and conflict management skills

### Evidence

There are several programs with evidence that support teaching social, emotional and parenting skills to reduce suicidal behaviors and associated risk factors.

- **Social emotional learning programs.** The *Youth Aware of Mental Health Program (YAM)* is a program developed for teenagers that uses interactive dialogue and role-playing to teach adolescents about the risk and protective factors associated with suicide (including knowledge about depression and anxiety) and enhances their problem-solving skills for dealing with adverse life events, stress, school and other problems. The program includes 3 hours of role-play sessions and interactive workshops combined with a booklet that students can keep, educational posters displayed in classroom, and interactive lectures about mental health at the beginning and end of the program (Wasserman et al., 2014). In a cluster-randomized controlled trial of YAM conducted across 10 European Union countries and 168 schools, students participating in the YAM program were significantly less likely to have an incident suicide attempt (OR 0.45, 95%CI 0.24–0.85;  $p=0.014$ ) and severe suicidal ideation (0.50, 0.27-0.92;  $p=0.025$ ) at the 12-month follow-up compared to the control group. Additionally, related to severe suicide ideation, in the YAM group absolute risk fell by 0.50% and RR fell by 49.6% (Wasserman et al., 2014).

*Signs of Suicide (SOS)* is another school-based prevention program for students aged 13-17. The program includes guided classroom discussions about suicide and depression. As part of the program, students are screened for depression and suicide risk and referred for professional help as indicated. The program is designed to increase knowledge about suicide and risk factors associated with suicidal behavior as well as improve and normalize help-seeking behavior (Schilling, Aseltine, & James, 2016). In a randomized controlled trial, SOS was shown to reduce self-reported suicide attempts at 3-months post intervention among

participating students compared to control students. The SOS program also increased students' knowledge of how to get help for themselves or friends for depression and/or suicidal thoughts, and favorable attitudes toward help-seeking. SOS participants with a lifetime history of suicide attempt were also less likely to report planning a suicide in the 3 months following the program compared to lower-risk participants (Schilling et al., 2016).

Finally, the *Good Behavior Game (GBG)* is a classroom-based program for elementary school children aged 6-10; it represents an example of upstream suicide prevention programming. The program uses a team-based behavior management strategy that promotes good behavior by setting clear expectations for good behavior and consequences for maladaptive behavior. The goal of the GBG is to create an integrated classroom social system that is supportive of all children being able to learn with little aggressive or disruptive behavior (Wilcox et al., 2008). In an outcome evaluation of the GBG, first graders assigned to GBG reported half the adjusted odds of suicidal ideation and suicide attempts. The beneficial effect of the program was consistent for suicidal ideation regardless of whether baseline covariates were included. The GBG effect on attempts was less robust in some adjusted models including caregiver mental health. In the second cohort of GBG students, neither suicidal ideation nor suicide attempts were significantly different between GBG and the control interventions (Wilcox et al., 2008). This finding likely arose due to the lack of implementation fidelity and pointed to the need for GBG to be delivered with precision, consistency, and teacher support. GBG was also found to be associated with reduced risk of later substance abuse, a risk factor for suicide (Kellam et al., 2008).

- **Parenting skill and family relationship programs.** Parenting and family skills training approaches have shown promising impacts in preventing key risk factors associated with suicide. For example, the *Incredible Years (IY)* is a comprehensive group training program for parents, teachers and children designed to reduce conduct and substance abuse problems, two important suicide risk factors, in youth by improving protective factors such as responsive and positive parent-teacher-child interactions and relationships, emotion self-regulation and social competence (all protective factors for suicide) (Herman et al., 2011). The program includes 9- 20 sessions offered in community-based settings (e.g., religious, recreation centers, mental health treatment centers, and hospitals). Several studies have demonstrated the effect of the IY program on reducing internalizing symptoms, such as anxiety and depression, and child conduct problems (C. H. Webster-Stratton, Reid, & Beauchaine, 2011; Webster-Stratton, Jamila Reid, & Stoolmiller, 2008). The program is also associated with improved problem-solving and conflict management; these skills were maintained at 1-year follow-up (Reid, Webster-Stratton, & Hammond, 2003; C. Webster-Stratton & Hammond,

1997; C. Webster-Stratton, Reid, & Hammond, 2001). The program demonstrated greater benefits as the dosage of the intervention increased (Herman et al., 2011).

Additionally, *Strengthening Families 10-14* is a program that involves sessions between parents, youth, and family with the goal of improving parents' skills for disciplining, managing emotions and conflict, and communicating with their children; promoting youths' interpersonal and problem-solving skills; and creating family activities to build cohesion and positive parent-child interactions. The premise of the program is that developing these skills for both parents and children will reduce internalizing behavior and adolescent substance abuse, two important risk factors for suicide (Spoth, Gyll, & Day, 2002). *Strengthening Families* has been shown to decrease externalizing behaviors, alcohol use, and drug use among youth participants and reductions in depression, alcohol use, and drug use among participating families (Spoth et al., 2002).

## Identify and Support People At-Risk

### Rationale

In order to decrease suicide, attention to people at increased or high risk is necessary as these individuals tend to experience suicidal behavior at higher than average rates. These vulnerable or disadvantaged populations include, but are not limited to, individuals with lower socio-economic status or who are living with a mental health problem; people who have attempted suicide previously, individuals who are institutionalized, have been victims of violence, or are homeless; and members of certain ethnic minority groups. Supporting these vulnerable groups requires proactive case finding along with access to, and retention in, mental health services. Finding effective ways of identifying at-risk or vulnerable groups, customizing services to make them accessible and maintaining care remain key challenges. For example, simply improving services does not guarantee that those services will be used by those most in need of them, nor will it necessarily increase the number of people who follow treatments that are recommended. People who are disadvantaged face social and economic issues that may adversely affect their ability to respond to the treatments or advice that are offered.

### Approaches

The following three approaches focus on identifying and supporting people at increased risk.

- **Gatekeeper training** is designed to train teachers, coaches, providers and others in the community to identify people who may be at risk of suicide and to respond effectively, including facilitating treatment seeking and support services. Gatekeeper training is typically implemented in schools to identify at-risk youth and within health care settings to identify adults (and youth).
- **Screening combined with care management and overall continuity of care** has been used in primary care and behavioral health care settings to assure that people who may be at high-risk of suicide are identified and receive ongoing treatment as needed, particularly after inpatient discharge and other transitions within the healthcare system so they don't 'slip through the cracks'. These approaches typically employ screening for depression and/or suicide combined with collaborative treatment planning between patients and their providers and patient follow-up.
- **Crisis intervention.** These approaches provide support and referral services, typically by connecting a person in crisis (or a friend or family member of someone at-risk) to trained volunteers and/or professional staff via telephone hotline, online chat, or text messaging. Crisis intervention approaches are intended to impact key risk factors for suicide, including feelings of depression, hopelessness, and subsequent mental health care utilization. Like means reduction,

crisis interventions can put space or time between an individual who may be considering suicide and harmful behavior.

### Potential Outcomes

- Reduction in suicide attempts
- Reduction in suicide deaths
- Increased identification of individuals at-risk for suicidal behavior
- Increased at-risk individuals in treatment
- Increased community members trained to identify at-risk individuals
- Increased referrals for health care

### Evidence

There is evidence that community gatekeeper programs are successful in reducing suicides and suicide attempts but the efforts must be maintained (Substance Abuse and Mental Health Services Administration, 2014). However, there is limited evidence for effectiveness screening programs, but at the same time, standard principles for public health screening make them promising (Pena & Caine, 2006). The number of studies evaluating crisis intervention services is limited, but a few studies do indicate that those who use the hotline services have decreased suicidal thoughts and behavior.

- **Gatekeeper training.** One example of gatekeeper training is the *Mental Health First Aid (MHFA)* program. This program is designed for the lay public and consists of three weekly sessions of three hours each. Participants learn the symptoms of people in mental health crises and/or in the early stages of mental health problems (i.e., those experiencing suicidal thoughts and behavior, acute stress reaction, panic attacks and acute psychotic behavior, and depression, anxiety, and psychotic disorders), possible risk factors, and where and how to get evidence-based effective help (Kitchener & Jorm, 2004). In a randomized controlled trial of 300 participants of *MHFA*, the intervention group reported greater confidence in providing help to others, greater likelihood of advising people to seek professional help, improved concordance with health professionals about treatments, and decreased stigmatizing attitudes. Additionally, the intervention resulted in improved mental health of the participants themselves. All results were statistically significant at  $p < .05$ . (Kitchener & Jorm, 2004). Additional research rigorously evaluating *MHFA* for its impact on the first aid recipients themselves and suicidal behavior is needed (Kitchener & Jorm, 2006).

Gatekeeper training has also been a core part of all *Garret Lee Smith (GLS) Suicide Prevention Program* which is in place in 49 states and 48 tribes. A multi-site evaluation assessed the

connection between community gatekeeper training and a reduction of suicide attempts and deaths by comparing the change in suicide mortality rates and nonfatal suicidal behavior among the population aged 10-24 in counties implementing GLS trainings, with the trajectory observed in similar counties that did not implement these trainings. Counties implementing GLS trainings had significantly lower youth suicide rates the year following the training implementation (-1.07,  $p=.03$ ) (Walrath, et al., 2015). This finding represents a decrease of 1 suicide death per 100,000 10 to 24 year olds or the avoidance of approximately 237 deaths in this age group between 2007 and 2010. Counties implementing GLS program activities also had significantly lower suicide attempt rates among youths 16 to 23 years of age in the year following implementation of the GLS program than did similar counties that did not implement GLS program activities (4.9 fewer attempts per 1000 youths [95% CI, 1.8-8.0 fewer attempts per 1000 youths];  $p = .003$ ; Godoy Garraza et al., 2015). More than 79 000 suicide attempts may have been averted during the period studied following implementation of the GLS program.

- Screening combined with care management and overall continuity of care.** The *Henry Ford Perfect Depression Care* program was the pre-cursor to *Zero Suicide*, and its overall goal was to eliminate suicide. More broadly, though, the aim was to completely redesign depression care delivery to achieve breakthrough improvement in quality and safety by focusing on six aims: effectiveness, safety, patient centeredness, timeliness, efficiency, and equity among patients. The program developed concrete measures to assess progress on each of these aims and began with screening and assessment of each patient for suicide risk with coordinated continuous follow-up care system wide (C. E. Coffey, 2006). An examination of the impact of the *Henry Ford Perfect Depression Care (Pre-cursor to Zero Suicide)* program found that there was a dramatic and statistically significant decrease in the rate of suicide between the baseline years prior to the intervention (1999 and 2000) to the intervention years (2002-2009). During this time period, the suicide rate fell 82% (C. E. Coffey, 2006; C. E. Coffey, Coffey, & Ahmedani, 2013). Further, suicide rates also declined among HMO members who participated in targeted suicide prevention efforts and received mental health specialty services. However, for those HMO members who accessed only general medical services as opposed to specialty mental health services, the suicide rate increased (M. Coffey, Coffey, & Ahmedani, 2015).
- Crisis intervention.** Suicide prevention hotlines are one way to provide crisis intervention. In an evaluation of the effectiveness of the *National Suicide Prevention Lifeline (NSPL)* to prevent suicide, 1,085 suicidal individuals who called the hotline completed a standard risk assessment for suicide, and 380 of those completed a follow-up assessment between 1 and 52 days after the initial assessment. Researchers found that over half of the initial sample were seriously considering suicide when they called, and they had a plan for their suicide. Researchers also found that participants experienced significant decreases in suicidality over the course of the

telephone session, and that levels of hopelessness and psychological pain continued to decrease after their initial call (Gould, Kalafat, Harrismunfakh, & Kleinman, 2007).

In another study, this time employing a randomized controlled trial, Gould, Cross, Pisani, Munfakh, and Kleinman (2013) assessed the impact of the *Applied Suicide Intervention Skills Training (ASIST)*, a widely implemented training program that helps hotline counselors, emergency workers, and other gatekeepers to identify and connect with suicidal individuals, understand their reasoning for living and dying, and assist with safely connecting those in need to available resources. The training was evaluated across the NSPL network of hotlines over the period 2008-2009. Using data from 1,410 suicidal individuals who called 17 Lifeline centers, researchers found that compared to callers who spoke to counselors that received the usual care training, individuals who spoke with counselors trained in *ASIST* were significantly more likely to feel less depressed, less suicidal, less overwhelmed, and more hopeful by the end of their call to the hotline. Counselors trained in *ASIST* were also more skilled at keeping callers on the phone longer and establishing a connection with them. However, training in *ASIST* did not result in more comprehensive suicide risk assessments than usual care training (Gould et al., 2013).

## Intervene to Lessen Harms and Prevent Future Risk

### Rationale

Individuals who have experienced mental health challenges, suicidal ideation, and/or who have made suicide attempts and/or have engaged in non-suicidal self-injury are at increased risk of suicide (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012). Risk of suicide can also increase among those who have lost a friend, family member, co-worker, or other acquaintance to suicide (Pitman, Osborn, King, & Erlangsen, 2014). Exposure to sensationalized or uninformed reporting regarding on suicide may heighten the risk of suicide among vulnerable individuals and can inadvertently contribute to suicide contagion (Etzersdorfer & Sonneck, 1998; Niederkrotenthaler & Sonneck, 2007).

### Approaches

A broad array of approaches to lesson harms and reduce future risk of suicide among those at increased risk include the provision of mental health care and improved continuity of care, improving linkage to care through active post-discharge planning and follow-up that decreases barriers to ongoing therapeutic support, increasing connectedness to supportive others, addressing bereavement, and framing communications to emphasize resilience, decrease negative affect, and to prevent contagion.

- **Treatment for people at-risk of suicide** typically includes various forms of psychotherapy delivered by licensed providers to help individuals with mental health problems and other risk factors for suicide with problem-solving, impulsivity and emotion regulation.
- **Treatment to prevent re-attempts.** These approaches typically include follow-up contact and use diverse modalities (e.g., home visits, mail, telephone, e-mail) to engage recent suicide attempt survivors in continued treatment to prevent re-attempts. Treatment may focus on improved coping skills, mindfulness, and other emotional regulation skills, and may include case management home visits to increase adherence to treatment and continuity of care; and one-on-one interpersonal therapy and/or group therapy. Approaches that engage and connect attempters to peers and providers are especially important because many attempters do not present to aftercare; 12%-25% reattempt within a year, and 3%-9% of attempt survivors die by suicide within 1 to 5 years of their initial attempt (Inagaki et al., 2015)
- **Postvention** approaches are implemented *after* a suicide has taken place and may include debriefing sessions, counseling, and/or bereavement support groups for surviving friends and family members/loved ones. These programs have not typically been evaluated for their impact on suicide or suicidal behavior but may reduce survivors' guilt, feelings of depression, and complicated grief (Szumilas & Kutcher, 2011).

- **Safe messaging following a suicide.** The manner in which information on a recent suicide is communicated to the public (e.g. school assemblies, mass media, social media) can heighten the risk of suicide among vulnerable individuals and can inadvertently contribute to suicide contagion. Therefore, responsible and safe reporting may help prevent suicide and/or suicide contagion.

### Potential Outcomes

- Reduction in mental health-related sequelae
- Increase connectedness
- Improved coping skills
- Improved messaging following suicide
- Reduction in re-attempts

### Evidence

The evidence addressing strategies to lesson harm and prevent future risk of suicide includes the evaluation of effects of specific approaches on risk and protective factors as well as suicide-related mortality. However, because the evaluation of suicide-related mortality requires large sample sizes and extended follow-up, much of the evidence in this area primarily focuses on risk and protective factors.

- **Treatment for people at-risk of suicide.** There are a number of treatments with evidence of impact on risk and protective factors for suicide. One example is the *Improving Mood – Promoting Access to Collaborative Treatment (IMPACT)* program. IMPACT aims to prevent suicide among older primary care patients by reducing suicide ideation and depression in primary care settings. It facilitates the development of a therapeutic alliance, a personalized treatment plan that includes patient preferences, as well as proactive follow-up (biweekly during an acute phase and monthly during continuation phase) by a depression care manager (Hunkeler et al., 2006). The program has been shown to significantly improve quality of life, and to reduce functional impairment, depression and suicidal ideation over 24-months of follow-up (Hunkeler et al., 2006; Unutzer et al., 2006) relative to patients who received care as usual.

Another example is *Collaborative Assessment and Management of Suicidality (CAMS)*, which is a therapeutic approach for suicide-specific assessment and treatment of patient's suicide risk. This flexible approach can be used across treatment settings and clinician theoretical orientations and involves the clinician and patient working together in an interactive assessment process to develop patient-specific treatment plans. CAMS sessions are collaborative and involve constant

**Comment [A]:** The write-up of the evidence for this strategy needs to follow the format used in the other sections of the TP. I modified the write-up for the first approach to illustrate the format. You will need to do something similar for the second approach.

patient about what is and is not working with the ultimate goal of enhancing the therapeutic alliance and increasing treatment motivation in the suicidal patient. CAMS been tested and supported in 6 correlational studies (Jobes, 2012), in a variety of inpatient and outpatient settings and in one RCT with several additional RCTs under way. CAMS has been associated with significant improvements in suicidal ideation, overall symptom distress, and feelings of hopelessness at 12 month follow-up among a community-based sample of suicidal outpatients. (Comtois et al., 2011).

Other examples include *Dialectical Behavioral Therapy (DBT)* and *Attachment-Based Family Therapy (ABFT)*. DBT is a multicomponent therapy for individuals at high risk for suicide and who may struggle with impulsivity and emotional regulation. The components of DBT include individual therapy, group skills training, between-session telephone coaching and a therapist consultation team. In a randomized controlled trial of women with recent suicidal or self-injurious behavior, those receiving DBT were half as likely to make a suicide attempt at two-year follow-up than women receiving community treatment (23% vs 46%), required less hospitalization for suicide ideation, and had lower medical risk across all suicide attempts and self-injurious acts combined (Linehan et al., 2006).

ABFT is a program for adolescents aged 12-18 and is designed to treat clinically diagnosed major depressive disorder, eliminate suicidal ideation, and reduce dispositional anxiety (Diamond et al., 2010). A randomized controlled trial of ABFT found that suicidal adolescents assigned to ABFT experienced significantly greater improvement in suicidal ideation over 24 weeks of follow-up than did adolescents assigned to enhanced usual care (-4.37 vs. -2.34;  $p = .001$ ;  $d=0.97$ ). Additionally, a higher percentage of ABFT participants reported no suicidal ideation in the week prior to assessment at 12 weeks than did adolescents receiving enhanced usual care (69.2% vs. 34.6%;  $p = .01$ ; OR= 4.25) and at 24 weeks (82.1% vs. 46.2%;  $p = .006$ ; OR=5.37) (Diamond et al., 2010).

- **Treatment to prevent re-attempts.**

**Emergency Department Brief Intervention with Follow-up Visits** is a program that involves a one-hour discharge information session that addresses suicidal behavior, distress, risk and protective factors, alternatives to suicidal behavior, and referral options, combined with nine follow-up contacts over 18-months (at 1, 2, 4, 7, 11 weeks and 4, 6, 12, 18 months). Follow-up contacts are either conducted by phone or through home visits according to a specific time line for up to 18-months. A randomized controlled trial that enrolled suicide attempters from eight hospital emergency departments in five culturally different sites found that a brief intervention combined with 9 follow-up visits over 18-months was associated with significantly fewer deaths

from suicide relative to a treatment-as-usual group (0.2% versus 2.2%, respectively;  $\chi^2 = 13.83$ ,  $P < 0.001$ ) (Fleischmann et al., 2008).

**Active follow-up contact approaches** such as postcards, letters, and telephone calls, are intended to increase a patient's sense of connectedness with health care providers and decrease isolation. These approaches include expression of care and support and typically invite patients to reconnect with their provider. Contacts are made periodically (e.g., monthly or every few months in the first 12 months post-discharge with some programs continuing contact for 2 or more years). These approaches have been found in a meta-analysis conducted by Inagaki et al. (2015) to reduce reattempts by approximately 17% for up to 12 months post-discharge, however, the long-term effects of these approaches on reattempts has not yet been demonstrated. Also, because the number of trials and associated sample sizes included in this meta-analysis were small, it was not possible to determine the effect of active contact and follow-up approaches on death by suicide. In a randomized controlled trial of post-crisis suicide prevention long-term follow-up contact approach, Motto and Bostrom (2001) found that patients who refused ongoing care but who were randomized to be contacted by letter four times per year had a lower rate of suicide over two years of follow-up than did patients in the control group who received no further contact. Other studies have also shown post-crisis letters and coping cards to be protective against suicide ideation and attempts (Hassanian-Moghaddam, Sarjami, Kolahi, & Carter, 2011; Wang et al., 2016).

**Cognitive Behavior Therapy for Suicide Prevention (CBT-SP)** uses a risk reduction, relapse prevention approach that includes an analysis of proximal risk factors and stressors (e.g., relationship problems, school or work-related difficulties) leading up to and following the suicidal event; safety plan development; skill building; and psychoeducation. *CBT-SP* also has family skill modules focused on family support and communication patterns as well as improving the family's problem solving skills. A randomized controlled trial found of *CBT-SP* found that 10-session outpatient cognitive therapy designed to prevent repeat suicide attempts resulted in a 50% reduction in the likelihood of a suicide reattempt among adults who had been admitted to an emergency department for a suicide attempt relative to treatment as usual (Brown et al., 2005).

- **Postvention** programs such as *StandBy Response Service* are implemented with the goal of providing support to survivors of suicide. *StandBy* provides clients with face-to-face outreach and telephone support through a professional crisis response team. Site coordinators develop customized case management plans, referring clients to other existing community services matched to their needs (Visser, Comans, & Scuffham, 2014). In a study by Visser et al. (2014), *StandBy* clients were significantly less likely to be at high risk for suicidality than a suicide bereaved comparison group who had not had contact with the *StandBy* program (48% and 64% respectively,  $p = 0.005$ ). Additionally, research suggests that active postvention approaches in

which outreach to suicide survivors occurs at the scene of a suicide is associated with intake into treatment sooner, greater attendance at support group meetings, and attendance at more meetings compared to passive postvention (versus passive approaches where survivors self-refer for services) (J. Cerel & Campbell, 2008).

- **Safe messaging following a suicide.** *Media guidelines* for reporting on suicides can help assure that stories on suicide are communicated in a safe and effective way. Reports that are both inclusive of suicide prevention messages, stories of hope and resilience, risk and protective factors, and links to helping resources (e.g., hotline) and that avoid sensationalizing events or reducing suicide to one cause can help reduce the likelihood of suicide contagion. The most compelling evidence supporting the effect of *media guidelines* on reduction in suicides comes from Austria. After a sharp increase in suicides on the Viennese subway, media guidelines were introduced and an interrupted time series design was used to evaluate the national impact of the guidelines on subsequent suicides. Changes in the quality and quantity of media reporting resulted in a reduction of 81 suicides annually (95% confidence interval: -149 to -13;  $t = -2.32$ ,  $df = 54$ ,  $p < 0.024$ ) in the Viennese subway system (Niederkrotenthaler & Sonneck, 2007)

## Sector Involvement

Public health can play an important and unique role in addressing suicide. Public health agencies, which typically place prevention at the forefront of efforts and work to create broad population-level impact, can bring critical leadership and resources to bear on this problem. For example, these agencies can serve as a convener, bringing together partners and stakeholders to plan, prioritize, and coordinate suicide prevention efforts. Public health agencies are also well positioned to collect and disseminate data, implement preventive measures, evaluate programs, and track progress. Although public health can play a leadership role in preventing suicide, the strategies and approaches outlined in this technical package cannot be accomplished by the public health sector alone.

Other sectors vital to implementing this package include, but are not limited to, education, government (local, state, and federal), social services, health services, business/labor, justice, housing, media, and organizations that comprise the civil society sector such as faith-based organizations, youth-serving organizations, foundations, and other non-governmental organizations. Collectively, these sectors can make a difference in preventing suicide by impacting the various contexts and underlying risks that contribute to suicide.

The strategies and approaches described in this technical package are summarized in Appendix A along with the relevant sectors that are well positioned to lead implementation efforts.

[Linda to insert text specific to the strategies and approaches]

Regardless of strategy, action by many sectors will be necessary for the successful implementation of this package. In this regard, all sectors can play an important and influential role in creating safe and protective environments where individuals who are at high risk of suicide can easily access the mental healthcare and services they need.

## Monitoring and Evaluation

Monitoring and evaluation are necessary components of the public health approach to prevention. It is important to have timely and reliable data to monitor the extent of the problem and to evaluate the impact of prevention efforts. Data are necessary for program implementation; planning, implementation, and assessment all rely on accurate measurement of the problem.

Surveillance data helps researchers and practitioners track changes in the burden of suicide. Surveillance systems exist at the federal, state, and local levels. It is important to assess the availability of surveillance data and data systems across these levels to identify and address gaps in the systems. CDC's National Vital Statistics System and the National Violent Death Reporting System (NVDRS) are examples of surveillance systems that provide data on deaths from suicide. NVDRS, for example, is a state-based surveillance system that combines data from death certificates, law enforcement reports, and coroner or medical examiner reports to provide detailed information on the circumstances of violent deaths, including suicide, which can assist communities in guiding prevention approaches (Blair, Fowler, Jack, & Crosby, 2016). The National Electronic Injury Surveillance System-All Injury Program (NEISS-AIP) provides nationally representative data about all types and causes of nonfatal injuries treated in U.S. hospital emergency departments, and can be used to assess national rates of, and trends in, self-harm injuries by cause (e.g., falls, poisoning, etc.), age, race/ethnicity, sex, disposition (where the injured person goes when released from the Emergency Department).

In addition to information on deaths and nonfatal injuries, there are also surveillance systems that provide national, state, and some local estimates of suicidal behavior. The Youth Risk Behavior Surveillance System (YRBSS) collects information from a nationally representative sample of 9-12 grade students and is a key resource in monitoring health-risk behaviors among youth, including whether youth have seriously considered attempting suicide, attempted suicide, made a plan, or required treatment by a doctor or nurse for a suicide attempt that resulted in an injury, poisoning, or overdose (Brener et al., 2013). The YRBSS data are obtained from a national school-based survey conducted by CDC as well as school-based state, territorial, tribal, and large urban school district survey conducted by education and health agencies. The National Survey on Drug Use and Health (NSDUH) is an annual nationwide survey of individuals aged 12 years and older that provides national and state-level estimates of drug use and mental health-related issues, including suicide ideation and suicide attempts.

It is also important at all levels (local, state, and federal) to address gaps in responses, track progress of prevention efforts and evaluate the impact of those efforts, including the impact of this technical package. Evaluation data, produced through program implementation and monitoring, is essential to provide information on what does and does not work to reduce rates of suicide and its associated risk and protective factors. Theories of change and logic models that identify short, intermediate, and long-term outcomes are an important part of program evaluation.

The evidence-base for suicide prevention has advanced greatly over the last few decades. However, additional research is needed to understand the impact of prevention programs on preventing suicide, as opposed to merely examining the effectiveness of programs to impact risk factors associated with suicide. More research is also needed to examine the effectiveness of upstream and community-level strategies to prevent suicide at the population level. Lastly, it will be important for researchers to test the effectiveness of combinations of the strategies and approaches included in this package. Most existing evaluations focus on approaches implemented in isolation. However, there is potential to understand the synergistic effects within a comprehensive prevention approach. Additional research is needed to understand the extent to which combinations of strategies and approaches result in greater reductions in suicide than individual programs, practices, or policies.

## Conclusion

Suicide is a serious public health problem whose rates have been on the rise for more than a decade and whose costs stretch well into the billions of dollars each year. And while suicide is a rare outcome statistically, its human impact has a ripple effect that is far-reaching. Each of us likely interacts with suicide survivors, those with lived experience, and those with thoughts of suicide, on a daily basis—at home, at work, and in our communities. Suicide and suicide attempts are therefore public health issues of societal concern. Fortunately, like many public health problems, suicide is preventable, and fortunately more is being done to prevent suicide than ever before, as evidenced by the work of the National Action Alliance for Suicide Prevention, the release of the first world report on suicide, more timely surveillance data, and critical mention in the President’s FY17 budget, to name just a few examples. Unfortunately and unlike most other public health problems, suicide still struggles against stigma, shame, and secrecy related to help-seeking, mental illness, being a survivor, or someone with lived experience; misplaced fear of asking someone about their risk of suicide (versus the fear and consequence of not asking), and fear of taking up certain strategies known to be effective but perhaps unpopular; misinformation about suicide preventability, and disproportionate funding given the public health burden. Suicide also struggles against the right degree of awareness where too much information, for example by well-meaning reporters and others, may actually do harm.

In an effort to continue pushing the field and society further towards prevention, this technical package includes strategies and approaches that ideally would be used in a comprehensive fashion, in combination—in a multi-level, multi-sectoral way. This technical package includes strategies and approaches targeting upstream prevention, e.g., social emotional learning for children and youth, as well as strategies focused more downstream, e.g., cognitive behavioral treatment to prevent re-attempts. It includes universal, selective, and indicated strategies, or strategies that focus on the whole population regardless of risk to strategies that focus on those groups at highest risk. Importantly, this technical package extends the bounds of the typical prevention strategies to consider approaches at the outer

levels of the social ecology, e.g., policies to stabilize housing and community engagement initiatives. In short, care and attention has been paid to all aspects of suicide prevention.

While the evidence base continues to be built, the collection of programs, policies, and practices laid out here are available for implementation now. And in keeping with good public health practice, the intent is that monitoring and evaluation will play a key role in that implementation. Moreover, as new evidence becomes available, this technical package can be refined to reflect the current state of the science.

In closing, and in keeping with a message of resilience as spoken by those with lived experience, ‘hope, help, and healing is possible.’

## Appendix A: Summary of Strategies and Approaches to Prevent Suicide

Strategy	Approach/Program, Practice or Policy	Best Available Evidence			Lead Sectors <sup>1</sup>
		Suicide	Suicide Attempts or Ideation	Other Risk/Protective Factors for Suicide	
Strengthen economic supports	Strengthen household financial security				
	Unemployment benefit programs	✓			Government (local, state, Federal)
	Housing stabilization policies				
	The National Neighborhood Stabilization Program			✓	Government (local, state, Federal)
Strengthen access to mental health care	Coverage of mental health conditions in health insurance policies				
	Mental Health Parity Laws	✓		✓	Government (state, Federal)  Health care
Establish protective environments	Reducing access to lethal means among persons at-risk				
	Intervening at hot spots	✓			Government (local, state, Federal)
	Safe storage practices		✓	✓	Public Health
	Organizational policies and culture				
	Together for Life	✓			Business/Labor

		Best Available Evidence			
	<i>US Air Force Suicide Prevention Program</i>	✓		✓	Government (local, state, Federal)
	Community-based policies to reduce excessive alcohol use				
	<i>Alcohol outlet density</i>	✓		✓	Government (local, state, Federal)
Promote connectedness to protect against suicide	Peer norm approaches				
	<i>Sources of Strength</i>			✓	Public Health Social Services
	Community-engagement activities				
	<i>Greening vacant urban spaces</i>			✓	Public Health
Teach coping and problem- solving skills	Social emotional learning				
	<i>Youth Aware of Mental Health Program</i>		✓		Public Health
	<i>Signs of Suicide</i>		✓	✓	Education
	<i>Good Behavior Game</i>		✓	✓	
	Parenting skill and family relationship approaches				
	<i>The Incredible Years</i>			✓	Public Health
				Education	

		Best Available Evidence			
	<i>Strengthening Families 10-14</i>			✓	
Identify and support people at-risk	Gatekeeper training				
	<i>Mental Health First Aid</i>			✓	Public Health Healthcare Social Services
	Screening combined with care management				
	<i>Henry Ford Perfect Depression Care (Pre-cursor to Zero Suicide)</i>	✓		✓	Healthcare
	Crisis Intervention				
	<i>National Suicide Prevention Lifeline</i>		✓	✓	Public Health Social Services
	<i>Applied Suicide Intervention Skills Training</i>		✓	✓	
Treatment for people at risk of suicide					
	<i>Improving Mood – Promoting Access to Collaborative Treatment (IMPACT)</i>		✓	✓	Healthcare Social Services
	<i>Collaborative Assessment and Management of Suicidality (CAMS)</i>		✓	✓	

		Best Available Evidence			
Intervene to lessen harms and prevent future risk	<i>Dialectical Behavioral Therapy</i>		✓	✓	
	<i>Attachment-Based Family Therapy</i>		✓		
	Treatment to prevent re-attempts				
	<i>ED Brief Intervention with Follow-up Visits</i>	✓			Healthcare
	<i>Active follow-up contact approaches</i>	✓	✓		
	<i>CBT for Suicide Prevention</i>				
	Postvention				
	<i>StandBy Response Service</i>		✓		Healthcare
	Safe messaging following a suicide				
	<i>Media Guidelines</i>	✓			Public Health

<sup>1</sup>This column refers to the lead sectors well positioned to bring leadership and resources to implementation efforts. For each strategy, there are many other sectors such as non-governmental organizations that are instrumental to prevention planning and implementing the specific programmatic activities.

## Overview

This technical package represents a select group of strategies based on the best available evidence to help communities and states sharpen their focus on prevention activities with the greatest potential to prevent suicide. Broadly, the strategies represented include those with a focus on preventing suicide from happening in the first place as well as approaches to lessen the immediate and long-term effects of suicidal behavior for individuals, families, communities, and society. Specifically, the strategies include strengthening economic supports; strengthening access to mental health care; establishing protective environments; promoting connectedness to protect against suicide; teaching coping and problem-solving skills; identifying and supporting people at-risk; and intervening to lessen harms and prevent future risk.

This package supports the National Strategy for Suicide prevention, Goal 1, “Integrate and coordinate suicide prevention activities across multiple sectors and settings.” (p.29) It also supports the National Action Alliance for Suicide Prevention’s priority (2016) “To create and disseminate a framework for comprehensive community-based suicide prevention.”

Commitment, cooperation, and leadership from numerous sectors, including public health, education, justice, health care, social services, business/labor, and government can bring about the successful implementation of this package.

### What is a Technical Package?

A technical package is a compilation of a core set of strategies to achieve and sustain substantial reductions in a specific risk factor or outcome (Frieden, 2014). Technical packages help communities and states prioritize prevention activities based on the best available evidence. This technical package has three components. The first component is the **strategy** or the preventive direction or actions to achieve the goal of preventing suicide. The second component is the **approach**. The approach includes the specific ways to advance the strategy. This can be accomplished through *programs, policies, and practices*. The approaches included come primarily from studies based in the United States. The **evidence** for each of the approaches in preventing suicide or its associated risk factors is included as the third component. This package is intended as a resource to guide and inform prevention decision-making in communities and states.

### Preventing Suicide is a Priority

Suicide, as defined by the Centers for Disease Control and Prevention (CDC), is part of a broader class of behavior called *self-directed violence*. Self-directed violence refers to behavior directed at oneself that deliberately results in injury or the *potential* for injury (Crosby, Ortega, & Melanson, 2011). Self-directed violence may be *suicidal* or *non-suicidal* in nature. For the purposes of this document, we refer only to behavior where suicide is intended.

- **Suicide** is a death caused by self-directed injurious behavior with any intent to die as a result of the behavior.
- **Suicide attempt** is defined as a *non-fatal* self-directed and potentially injurious behavior with any intent to die as a result of the behavior. A suicide attempt may or may not result in injury.

### **Suicide is highly prevalent.**

Suicide presents a major challenge to public health in the United States and worldwide. It contributes to premature death, morbidity, lost productivity, and health care costs (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014). In 2014 in the U.S., the most recent death data available, suicide was responsible for 42,773 deaths, which is approximately one suicide every 12 minutes (Centers for Disease Control and Prevention, 2016d). In 2014, suicide ranked as the tenth leading cause of death and has been among the top twelve leading causes of death since 1975 in the U.S (Centers for Disease Control and Prevention, 2016d). Overall suicide rates have increased 24% from 1999 to 2014 (Curtin, Warner, & Hedegaard, 2016). Suicide is a problem throughout the life span; it is the second leading cause of death among those aged 10–19 years, also second among persons in their 20s and 30s; it is the fourth leading cause among persons in their 40s and seventh among persons in their 50s (Centers for Disease Control and Prevention, 2016d).

Suicides reflect only a portion of the problem (Crosby, Han, Ortega, Parks, & Gfroerer, 2011). Substantially more people are hospitalized as a result of nonfatal suicidal behaviors (i.e. suicide attempts) than are fatally injured, and an even greater number are either treated in ambulatory settings (e.g., emergency departments) or not treated at all (Crosby, Han, et al., 2011). For example, during 2014, among adults aged 18 years and older, for every one suicide there were 9 adults treated in hospital emergency departments for self-harm injuries, 27 who reported making a suicide attempt, and over 227 who reported seriously considering suicide (i.e. ideation) (Ferdon et al., In press). Suicides, suicide attempts, and ideation take an immense emotional, physical, and economic toll (see p. 9) on individuals, families and communities. By one conservative estimate, for every death by suicide six people are directly impacted (i.e. survivors). Based on this figure it is estimated that there are over 13 million survivors in the U.S. and unfortunately, survivorship itself is a risk factor for suicide (Crosby & Sacks, 2002).

### **Suicide is associated with several risk and protective factors.**

Suicide, like other human behaviors, is complex with no single determining cause. Instead, suicide occurs in response to multiple biological, psychological, interpersonal, environmental and societal influences that interact with one another, often over time. The social-ecological model is a useful framework for viewing and understanding suicide risk factors identified in the literature (Dahlberg & Krug, 2002):

Some risk Factors for suicide include (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014):

- **Individual:** History of depression and other mental illnesses, alcohol and drug abuse, previous suicide attempt, violence victimization, genetic and biological determinants, hopelessness
- **Relationship:** High conflict or violent relationships, sense of isolation and lack of social support, family/loved one's history of suicide, financial and work stress
- **Community:** Inadequate community connectedness, barriers to health care (e.g., lack of access to providers and medications)
- **Societal:** Availability of lethal means of suicide, unsafe media portrayals of suicide, stigma associated with help-seeking and mental illness

It is important to recognize that the vast majority of individuals who are depressed (or who have other risk factors) do *not* die by suicide. Furthermore, the relevance of each risk factor can vary by age, race, gender, sexual orientation, residential geography, and socio-cultural and economic status (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014)

Protective factors, or those influences that guard *against* the risk for suicide, can also be found across the different levels of the social-ecological model. Protective factors identified in the literature include: effective coping and problem solving skills, moral objections to suicide, strong and supportive relationships with partners, friends, and family; connectedness to school, community and other social institutions; availability of quality and ongoing physical and mental health care, and reduced access to lethal means (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014). These protective factors can either counter a specific risk factor or guard against a number of risks associated with suicide.

### **Suicide is connected to other forms of violence.**

As indicated above, suicide is connected to other forms of violence. Suicide and other forms of violence often share some of the same root causes (Butchart, Phinney, Check, & Villaveces, 2004; Klevens, Simon, & Chen, 2012). For example, in neighborhoods where there is low social cohesion, or where residents don't support and trust each other, people are at higher risk for suicide (Desai, Dausey, &

Rosenheck, 2005) as well as perpetration of child maltreatment (Coulton, Crampton, Irwin, Spilsbury, & Korbin, 2007; Freisthler, Merritt, & LaScala, 2006), teen dating violence (Capaldi, Knoble, Shortt, & Kim, 2012), intimate partner violence (Pinchevsky & Wright, 2012), and youth violence (Sampson, Morenoff, & Gannon-Rowley, 2002). Additionally, a lack of economic opportunities and unemployment are associated with suicide (Luo, Florence, Quispe-Agnoli, Ouyang, & Crosby, 2011; Reeves et al., 2012), as well as perpetration of child maltreatment (D. Runyan, Wattam, Ikeda, Hassan, & Ramiro, 2002), intimate partner violence (Heise & Garcia-Moreno, 2002; Pinchevsky & Wright, 2012), sexual violence (Centers for Disease Control and Prevention, 2016c) and youth violence (Wilson, 2011). Other shared risk factors for suicide and violence occur at the individual level and include substance abuse, mental health problems, witnessing violence, and a lack of problem-solving skills (Centers for Disease Control and Prevention, 2016a, 2016c, 2016e; U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012).

Just as risk factors may be shared across suicide and violence, so too may protective factors overlap. For example, connectedness increases individual's and communities' resilience to suicide and other forms of violence, including connectedness to one's community (Basile, Hamburger, Swahn, & Choi, 2013; Borowsky, Hogan, & Ireland, 1997; Centers for Disease Control and Prevention, 2016b; Coulton et al., 2007; Kleiman, Riskind, Schaefer, & Weingarden, 2012; Pinchevsky & Wright, 2012; Widome, Sieving, Harpin, & Hearst, 2008), school (Basile, Espelage, Rivers, McMahon, & Simon, 2009; Capaldi et al., 2012; Carter, McGee, Taylor, & Williams, 2007; DeGue et al., 2013; Hong, Kral, Espelage, & Allen-Meares, 2012; Losel & Farrington, 2012), family (Capaldi et al., 2012; Centers for Disease Control and Prevention, 2016a; Elgar, Craig, Boyce, Morgan, & Vella-Zarb, 2009; Maimon, Browning, & Brooks-Gunn, 2010; Resnick, Ireland, & Borowsky, 2004), caring adults (Capaldi et al., 2012; Losel & Farrington, 2012; Maimon et al., 2010), and pro-social peers (Capaldi et al., 2012; Losel & Farrington, 2012).

### **The health and economic consequences of suicide are substantial.**

Suicide and suicide attempts have far-reaching consequences for individuals, families, and communities (Dunne, McIntosh, & Dunne-Maxim, 1987; Mishara, 1995; National Action Alliance for Suicide Prevention: Suicide Attempt Survivors Task Force, 2014; National Action Alliance for Suicide Prevention: Survivors of Suicide Loss Task Force, 2015). Research indicates that the health consequences of violence, including suicide, are much more extensive than injury and death. Suicide attempt survivors (i.e. those with lived experience) may suffer long-term health and mental health consequences ranging from anger, guilt, and physical impairment, depending on the means and severity of the attempt (Chapman & Dixon-Gordon, 2007). Similarly, survivors of a loved one's suicide may experience ongoing pain and suffering including complicated grief (Mitchell, Kim, Prigerson, & Mortimer-Stephens, 2004), stigma, depression, anxiety, post-traumatic stress disorder, and increased risk of suicidal ideation and suicide (Julie Cerel, McIntosh, Neimeyer, Maple, & Marshall, 2014; Sudak, Maxim, & Carpenter, 2008).

The economic toll of suicide is immense as well. The total lifetime costs associated with nonfatal injuries and deaths caused by self-directed violence in 2013 were approximately \$93.5 billion after adjusting for under-reporting of suicide (Shepard, Gurewich, Lwin, Reed, & Silverman, 2016). The overwhelming burden of these costs results from lost productivity over the life course, with the average cost per suicide being over \$1.3 million (Shepard et al., 2016).

### **Suicide can be prevented.**

Despite the myths surrounding suicide, like most public health problems, suicide is preventable (U.S. Public Health Service, 1999). And while progress will continue to be made into the future, evidence for numerous programs, practices, and policies currently exists, and many programs are ready to be implemented now. Just as suicide is not caused by a single factor, research suggests that suicide will not be prevented by any single intervention taking place in any single setting (Silverman & Maris, 1995; U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012). Rather, suicide prevention is best achieved by a focus across the individual-, relationship-, family-, community, and societal-levels and across all sectors, private and public (e.g., business, public health, physical and behavioral healthcare, justice, education, labor) (National Action Alliance for Suicide Prevention, 2014; World Health Organization, 2014). According to Frieden (2014), successful public health programs also require political commitment, funding, communication, and performance monitoring.

### **Assessing the Evidence**

This technical package includes programs, practices, and policies with evidence of impact on suicide or risk or protective factors for suicide. To be considered for inclusion in the technical package, the program, practice, or policy selected had to meet at least one of these criteria: a) meta-analyses or systematic reviews showing impact on suicide; b) evidence from at least one rigorous (e.g., randomized controlled trial [RCT] or quasi-experimental design) evaluation study that found significant preventive effects on suicide; c) meta-analyses or systematic reviews showing impact on risk or protective factors for suicide, or d) evidence from at least one rigorous (e.g., RCT or quasi-experimental design) evaluation study that found significant impacts on risk or protective factors for suicide. Finally, consideration was also given to the likelihood of achieving beneficial effects on multiple forms of violence; no evidence of harmful effects on specific outcomes or with particular subgroups; and feasibility of implementation in a U.S. context if the program, policy, or practice has been evaluated in another country.

Within this technical package, some approaches do not yet have research evidence demonstrating impact on rates of suicide but instead are supported by evidence indicating impacts on risk or protective factors for suicide (e.g., help-seeking, stigma reduction, depression, connectedness). In terms of the strength of the evidence, programs that have demonstrated effects on suicidal behavior (e.g., reductions in deaths, attempts) provide a higher-level of evidence, but the evidence base is not that strong in all areas. For instance, there has been less evaluation of community engagement and

family programs on suicidal behavior. Thus, approaches in this package that have effects on risk or protective factors reflect the developmental nature of the evidence base and the use of the best available evidence at a given time.

It is also important to note that there is often significant heterogeneity among the programs, policies, or practices that fall within one approach or strategy area in terms of the nature and quality of the available evidence. Not all programs, policies, or practices that utilize the same approach (e.g., gatekeeper training) are equally effective, and even those that are effective may not work across all populations. Tailoring programs and more evaluation may be necessary to address different population groups. The examples provided are not intended to be a comprehensive list of evidence-based programs, policies, or practices for each approach, but rather illustrate models that have been shown to impact suicide or have beneficial effects on risk or protective factors for suicide. In practice, the effectiveness of the programs, policies and practices identified in this package will be strongly dependent on the quality of their implementation and the communities in which they are implemented. Implementation guidance to assist practitioners, organizations and communities will be developed separately.

### Context and Cross-Cutting Themes

The strategies and approaches that have been included in this technical package represent different levels of the social ecology, with efforts intended to impact the community and societal levels, as well individual and relationship levels. The strategies and approaches are intended to work in combination and reinforce each other to prevent suicide (see box below). The strategies are arranged in order such that those strategies hypothesized to have the greatest potential for broad public health impact on suicide are included first, followed by those that might impact more select populations (e.g., persons who have already made a suicide attempt).

Preventing Suicide	
Strategy	Approach
Strengthen economic supports	<ul style="list-style-type: none"> <li>Strengthen financial security</li> <li>Housing stabilization policies</li> </ul>
Strengthen access to mental health care	<ul style="list-style-type: none"> <li>Coverage of mental health conditions in health insurance policies</li> </ul>
Establish protective environments	<ul style="list-style-type: none"> <li>Means restriction</li> <li>Organizational policies and culture</li> <li>Community-based policies to reduce excessive alcohol use</li> </ul>
Promote connectedness to protect against suicide	<ul style="list-style-type: none"> <li>Peer norm approaches</li> <li>Community engagement activities</li> </ul>

Teach coping and problem-solving skills	<ul style="list-style-type: none"> <li>• Social-emotional learning</li> <li>• Parenting skill and family relationship approaches</li> </ul>
Identify and support people at risk	<ul style="list-style-type: none"> <li>• Gatekeeper training</li> <li>• Screening combined with care management</li> <li>• Crisis intervention</li> </ul>
Intervene to lessen harms and prevent future risk	<ul style="list-style-type: none"> <li>• Treatment for people at-risk of suicide</li> <li>• Treatment to prevent re-attempts</li> <li>• Postvention</li> <li>• Safe messaging following a suicide</li> </ul>

The example programs, policies, and practices have been implemented within particular contexts. The social and cultural context of communities is critically important to take into account when selecting strategies and approaches. Practitioners in the field may be in the best position to assess the needs and strengths of their communities and work with community members to make decisions about the combination of approaches included here that are best suited to their context.

Suicide ideation, attempts, morbidity and mortality vary by gender, race/ethnicity, age, occupation, and other important population characteristics. Barriers to disclosure, help seeking, timely access to quality care, and ongoing support are profoundly complex and may also vary by population and community characteristics. Ideally, the availability of multiple approaches tailored to the economic, cultural, and environmental context of individuals and communities are desirable as they may increase the likelihood of removing barriers to supportive and effective care and provide opportunities to develop individual and community resilience. These culturally appropriate approaches can then be included in comprehensive strategies to maximize the public health impact on reducing suicide-related morbidity and mortality among individuals and within communities.

This package includes strategies where public health agencies are well positioned to bring leadership and resources to implementation efforts. It also includes strategies where public health can serve as an important collaborator (e.g., strategies addressing community and societal level risks), but where leadership and commitment from other sectors such as business/labor or health care is critical to implement a particular policy or program (e.g., workplace policies; screening combined with care management). The role of various sectors in the implementation of a strategy or approach in preventing suicide is described further in the section on *Sector Involvement*.

In the sections that follow, the strategies and approaches with the best available evidence for preventing suicide are described.

## Strengthen Economic Supports

### Rationale

Public health research suggests that some of the biggest impacts on health come from policies developed to improve socioeconomic conditions (Frieden, 2010). Downturns in the economy and increases in unemployment and home foreclosures are associated with increased rates of suicide (Fowler, Gladden, Vagi, Barnes, & Frazier, 2015; Luo et al., 2011). Policies that strengthen financial security can help people stay in their homes, pay for necessities such as food and medical care, and get job training, among other things. In providing this support, stress and anxiety and the potential for a crisis situation may be reduced, thereby preventing suicide.

### Approaches

Economic and housing supports for individuals and families can be strengthened by improving policies that enhance financial security and stabilize housing for people, especially in times of economic need.

- **Strengthen household financial security.** Studies from the U.S. indicate that suicide rates increase during economic recessions marked by high unemployment rates, job losses, and economic instability and decrease during economic expansions and periods marked by low unemployment rates, particularly for working-age individuals 25 to 64 years old (Luo et al., 2011; Fowler et al., 2015). Policies that support financial security, such as provision of unemployment benefits, family assistance, education and training assistance, and other social welfare payments may help mitigate the risk of economic crises on suicide rates.

### Potential Outcomes

- Reduced suicide rates
- Lower foreclosure rates
- Lower eviction rates
- Reduced emotional distress

### Evidence

There is evidence that policies that strengthen household financial security and that stabilize housing can reduce suicide risk.

- **Strengthen household financial security.** Provision of *Unemployment benefits* are one means to strengthen financial security. These benefit programs provide income protection during periods of unemployment in an effort to prevent or lessen the economic hardship for those experiencing job loss and enduring unemployment. An examination of variations in U.S. *unemployment benefit programs* across states demonstrated that the impact of unemployment on suicide was offset in those states that provided greater than average unemployment

benefits (Cylus, Glymour, & Avendano, 2014). Another U.S. study examining the link between unemployment and suicide risk using monthly suicide data, length of unemployment, and job losses found that the duration of unemployment, as opposed to just the loss of job, predicted suicide risk (Classen & Dunn, 2012). Together, these results suggest that not only should state unemployment benefit programs be generous in their financial allocations, but also in their duration. Other social spending policies and programs have also shown an impact on suicide. A study by Flavin and Radcliff (2009) examined the impact of states' per capita spending on transfer payments (e.g., retirement and disability insurance benefits, income maintenance benefits, unemployment insurance compensation), medical benefits, family assistance (e.g., food and welfare programs), and total state spending on suicide rates between 1990-2000. A variety of suicide risk factors at the state level were also controlled in the analysis. What they found was that as per capita spending on total transfer payments, medical benefits, and family assistance increase there was an associated decrease in state suicide rates. Moreover, it wasn't spending in general that was associated with the reduction but spending on social programs specifically. In terms of lives saved, it was estimated that 3,000 fewer suicides would occur per year nationwide (Flavin & Radcliff, 2009). More research is needed to assess the impact of these policies in today's social and economic context, but evidence thus far is promising.

## Strengthen Access to Mental Health Care

### Rationale

Mental illness is a risk factor for suicide-- Studies suggest that up to 90% of people who die by suicide may have had a mental illness at the time of their deaths (Cavanagh, Carson, Sharpe, & Lawrie, 2003) and research on state-level suicide rates have been found to be correlated with general mental health measures such as depression (Arsenault-Lapierre, Kim, & Turecki, 2004). While most people with mental health problems do not attempt or die by suicide (Olfson, Gerhard, Huang, Crystal, & Stroup, 2015) and most people who have attempted suicide will not go on to die by suicide (Owens, 2002), assuring access to affordable mental health care for people in need is critical to suicide prevention.

### Approaches

A major approach to strengthening access to mental health care is through the provision of health insurance policies that include coverage for such services.

- **Coverage of mental health conditions in health insurance policies.** Historically, mental health care was viewed as separate from physical health care and many health insurance plans either did not provide coverage of mental health services or such services were available but not affordable--due to higher co-pays or co-insurance-- or set limits on the number of visits allowed. More recently, improvements have been made with many health insurance policies providing greater levels of mental health coverage and more provide coverage that is on par with coverage for other health concerns, i.e. mental health parity. These policies can help prevent suicide by increasing the accessibility and affordability, and ultimately the use of, needed mental health services. As more people access mental health services this helps normalize treatment seeking in the population, reduces symptoms of mental illnesses like depression and bipolar disorder, and in turn, reduce rates of suicide and suicide attempts.

### Potential Outcomes

- Increased utilization of mental health services
- Decreased symptoms of mental illnesses
- Decreased rates of suicide attempts
- Decreased rates of suicide

### Evidence

There is evidence suggesting that coverage of mental health conditions in health insurance policies can reduce risk factors associated with suicide and may directly impact suicide rates.

- **Coverage of mental health conditions in health insurance policies.** The National Survey of Drug Use and Health is a nationally representative survey of the U.S. population that provides

data on substance use, mental health conditions, and services utilization. Using data from this survey, Harris, Carpenter, and Bao (2006) found that 12 months after states enacted *mental health parity laws*, self-reported use of mental healthcare services significantly increased. Moreover, subsequent research by Lang (2013) examined state mental health laws and suicide rates between 1990 and 2004 and found that mental health parity laws, specifically, were associated with an approximate 5% reduction in suicide rates. This reduction, in the 29 states with parity laws, equated to the prevention of 592 suicides per year and a cost savings of \$1.3-3.1 million per suicide prevented (Lang, 2013).

## Establish Protective Environments

### Rationale

Prevention efforts that focus not only on individual behavior change (e.g., help-seeking, treatment interventions) but on changes to the environment (e.g., policy-level interventions, modifications to the environment) as well, increase the likelihood of success (Haddon, 1980). Protective environments may be defined in part, as those where risk factors associated with suicide are limited and where protective factors are encouraged. Examples of risk factors include easy access to lethal means, stigma related to help-seeking, and substance abuse (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012). Protective factors include such things as social connectedness and access to mental health services (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012). Establishing environments that address these factors where individuals live, work, and play, can help prevent suicide.

### Approaches

The current evidence suggests three promising approaches for creating environments that protect against suicide.

- **Reducing access to lethal means.** Means of suicide such as firearms, hanging/suffocation, or jumping from heights provide little opportunity for rescue and, as such, have high case fatality rates (e.g., about 85% of people who use a firearm in a suicide attempt will die from the injury). Research also indicates that 1) the interval between thinking about and attempting suicide can be as short as 5 or 10 minutes (Deisenhammer et al., 2009; Simon et al., 2001) and 2) that people tend *not* to substitute a different method when a highly lethal method is unavailable or difficult to access (Hawton, 2007; Yip et al., 2012). Therefore, increasing the time interval between the thought and the suicide attempt, for example, by making it more difficult to access lethal means, can be lifesaving. The following are examples of approaches reducing access to lethal means:
  - *Intervening at Suicide Hotspots.* Suicide hotspots, or places where suicides may take place relatively easily, include tall structures (e.g., bridges and cliffs), railway tracks, and isolated locations such as parks. Efforts to prevent suicide at these locations include erecting barriers to prevent jumping and installing signs and telephones to encourage individuals who are considering suicide, to seek help (Cox et al., 2013).
  - *Safe Storage Practices.* Safe storage of medications, firearms, and other household products can reduce the risk for suicide by separating individuals who may be vulnerable and/or impulsive from easy access to lethal means. Such practices may

include education and counseling around storing firearms--locked in a secure place (e.g., in a gun safe or lock box), preferably unloaded and separate from the ammunition--and keeping medicines in a locked cabinet or other secure location away from people who may be at risk or who have made prior attempts (Rowhani-Rahbar, Simonetti, & Rivara, 2016; C. W. Runyan et al., 2016).

- **Organizational policies and culture** that promote protective environments may be implemented in places of employment. Such policies and cultural values may promote prosocial behavior (e.g., asking for help), skill building, changing social norms, referral and access to helping services (e.g. mental health, substance abuse treatment, financial counseling), and encourage leadership support from the top down. Such policies and cultural shifts can positively impact organizational climate and morale and help prevent suicide and its related risk factors (e.g. depression, social isolation).
- **Community-based policies to reduce excessive alcohol use.** Research studies in the United States have found that greater alcohol availability is positively associated with alcohol-involved suicides (Escobedo & Ortiz, 2002; Giesbrecht et al., 2015). Policies to reduce excessive alcohol use broadly include zoning to limit alcohol outlet locations and density, taxes on alcohol, and bans on the sale of alcohol for individuals under the legal drinking age. These policies are important because acute alcohol use has been found to be associated with more than one-third of suicides and approximately 40% of suicide attempts (Cherpitel, Borges, & Wilcox, 2004).

### Potential Outcomes

- Increase in safe storage of lethal means
- Reduction in suicide attempts
- Reduction in suicide deaths
- Increase in help-seeking
- Reduction in alcohol-related suicide deaths

### Evidence

The evidence for the effectiveness of means restriction and other ways to establish protective environments is some of the strongest in the field (Zalsman et al., 2016), as described below.

- **Means restriction.** A meta-analysis examining the impact of *suicide hotspot interventions* implemented in combination or in isolation, both in the U.S. and abroad, found associated reduced rates of suicide (Cox et al., 2013; Pirkis et al., 2015). For example, after erecting a barrier on the Jacques-Cartier bridge in Canada, the suicide rate from jumping from the bridge decreased from about 10 suicide deaths per year to about 3 deaths per year (Perron, Burrows, Fournier, Perron, & Ouellet, 2013). Moreover, the reduction in suicides by jumping was

sustained even when all bridges and nearby jumping sites were considered, suggesting little to no displacement of suicides to other jumping sites (Perron et al., 2013). Further evidence for the effectiveness of bridge barriers was demonstrated by a study examining the impact of the *removal* of safety barriers from the Grafton Bridge in Auckland, New Zealand. After removal of the barrier, sadly, both the number and rate of suicide increased fivefold (Beautrais, 2001; Beautrais, Gibb, Fergusson, Horwood, & Larkin, 2009).

Another form of means reduction involves implementation of *safe storage practices*. In a case-control study of firearm-related events identified from 37 counties in Washington, Oregon, and Missouri, and from 5 trauma centers, Grossman et al. (2005) found that storing firearms unloaded, separate from ammunition, in a locked place and/or secured with a safety device was protective of suicide attempts among adolescents. Further, a recent systematic review of clinic and community-based education and counseling interventions suggested that the provision of safety devices significantly increased safe firearm storage practices compared to counseling alone or compared to the provision of economic incentives to acquire safety devices on one's own (Rowhani-Rahbar et al., 2016). Another program, *The Emergency Department Counseling on Access to Lethal Means (ED CALM)*, trained psychiatric emergency clinicians in a large children's hospital to provide lethal means counseling and safe storage boxes to parents of patients under age 18 receiving care for suicidal behavior. In a pre-post quality improvement project, Runyan et al. (2016) found that at post-test 76% (of the 55% of parents follow-up, n=114) reported that all medications in the home were locked up as compared to fewer than 10% at the time of the initial emergency department visit. Among parents who indicated the presence of guns in the home at pre-test (i.e. 67%), all (100%) reported guns were currently locked up at post-test (C. W. Runyan et al., 2016).

- **Organizational policies and culture.** *Together for Life* is a workplace program of the Montreal Police Force implemented to address suicide among officers. Policy and program components were designed to foster an organizational culture that promoted mutual support and solidarity among all members of the Force. The program included training of supervisors, managers and all units to improve competencies in identifying suicidal risk and to improve use and awareness of existing resources. The program also included an education campaign to improve awareness and help-seeking (Mishara & Martin, 2012). Police suicides were tracked over 12 years and compared to rates in the control city of Quebec. The suicide rate in the intervention group decreased significantly by 78.9% to a rate of 6.42 suicides per 100,000 population per year compared to an 11% increase in the control city (rate: 29.0 per 100,000) (Mishara & Martin, 2012).

Another example of this approach is the *United States Air Force Suicide Prevention Program (AFSPP)*. AFSPP included 11 policy and education initiatives and was designed to change the

culture of the Air Force surrounding suicide. The program uses leaders as role models and agents of change, establishes expectations for behavior related to awareness of suicide risk, develops population skills and knowledge (i.e., education and training), and investigates every suicide (i.e., outcomes measurement). The program represents a fundamental shift from viewing suicide and mental illness solely as medical problem and instead sees them as larger service-wide problems impacting the whole community (K. L. Knox, Litts, Talcott, Feig, & Caine, 2003). Using a time-series design to examine the impact of the AFSPP program on various violence-related outcomes, researchers found that the program was associated with a 33% relative risk reduction in suicide (K. L. Knox et al., 2003). The program was also associated with relative risk reductions in related outcomes including moderate and severe family violence (30% and 54%, respectively), homicide (51%), and accidental death (18%) (K. L. Knox et al., 2003). A longitudinal assessment of the program over the period 1981 to 2008 (16 years before the 1997 launch of the program and 11 years post-launch) found significantly lower rates of suicide after the program was launched than before (K. L. Knox et al., 2010). These effects were sustained over time, except in 2004, which the authors found was associated with less rigorous implementation in that year than in the other years (K. L. Knox et al., 2010).

- **Community-based policies to reduce excessive alcohol use.** While multiple policies to limit alcohol use exist, several studies on alcohol outlet *density*, specifically, suggest that measures to reduce alcohol outlet density can potentially reduce alcohol-involved suicides. Additionally, a longitudinal analysis of alcohol outlet density, suicide mortality, and hospitalizations for suicide attempts over 6 years in 581 California zip codes indicated that the density of bars, specifically, is related to suicide and suicide attempts, particularly in rural areas (Johnson, Gruenewald, & Remer, 2009).

## Promote Connectedness to Protect Against Suicide

### Rationale

Sociologist, Emile Durkheim theorized in 1897 that weak social bonds, i.e. lack of connectedness, are among the chief causes for suicidality (Durkheim, 1897/1951). *Connectedness* is the degree to which an individual or group of individuals are socially close, interrelated, or share resources with others (Centers for Disease Control and Prevention, 2009). Social connections can be formed within and between multiple levels of the social ecology (Dahlberg & Krug, 2002), for instance between individuals (e.g. peers, neighbors, co-workers), families, schools, neighborhoods, workplace, faith communities, cultural groups, and society as a whole. Related to connectedness, *social capital* refers to a sense of trust in one's community and neighborhood, social integration, and also the availability and participation in social organizations (Beyer, Layde, Hamberger, & Laud, 2015; Muennig, Cohen, Palmer, & Zhu, 2013). Many ecological cross-sectional and longitudinal studies have examined the impact of aspects of social capital on depression symptoms, depressive disorder, mental health more generally, and suicide. While the evidence is still being built the pattern is towards an inverse association between social capital measured by social trust, community/ neighborhood engagement, and improved mental health. Connectedness and social capital together can serve to protect against suicidal behaviors by decreasing isolation, encouraging adaptive coping behaviors, increasing belongingness, personal value and worth all of which helps individuals to build resilience in the face of adversity. Connectedness can also provide individuals with better access to formal supports and resources, mobilize communities to meet the needs of its members and provide collective primary prevention activities to the community as a whole (Centers for Disease Control and Prevention, 2009)

### Approaches

Promoting connectedness among individuals and within communities through modeling peer norms and enhancing community engagement can protect against suicide.

- **Peer norm approaches** seek to normalize prosocial behaviors/protective factors for suicide such as help-seeking, reaching out and talking to trusted adults, and peer connectedness. These approaches typically target youth and are delivered in school settings but can also be implemented in community settings.

- **Community engagement activities.** Community engagement is an aspect of social capital. Community engagement approaches may involve residents participating in a range of activities, including religious activities, community clean-up and greening activities, and physical exercise. These activities provide opportunities for residents to become more involved in the community and to connect with other community members, organizations, and resources, resulting in enhanced overall physical health, reduced stress, and decreased depressive symptoms, thereby reducing risk of suicide.

### Potential Outcomes

- Reduction in maladaptive coping attitudes and behaviors
- Increase in healthy coping attitudes and behaviors
- Increase in referrals for youth in distressed
- Increase help-seeking behaviors
- Positive perception of adult support

### Evidence

Current evidence suggests that peer norm approaches and community engagement can reduce risk factors associated with suicidal behaviors.

- **Peer norm approaches.** Evaluations show that programs such as *Sources of Strength* can improve school norms and beliefs about suicide that are created and disseminated by student peers. In a randomized controlled trial of *Sources of Strength* conducted with 18 high-schools (6 metropolitan, 12 rural), Wyman et al. (2010) found that the program improved peer leaders' adaptive norms regarding suicide, their connectedness to adults, and school engagement. Peer leaders were also more likely than controls to refer a suicidal friend to an adult. Among students, the intervention increased perceptions of adult support for suicidal youths and the acceptability of seeking help. Perception of adult support increased most in students with a history of suicidal ideation. Finally, trained peer leaders also reported a greater decrease in maladaptive coping attitudes compared with untrained leaders (Wyman et al., 2010).
- **Community engagement activities.** A vacant lot greening initiative was undertaken in Philadelphia between 1999 and 2008. Local residents and community members worked together to green 4,436 lots (or 7.8 million square feet) in 4 areas of the city. Researchers found significant associated reductions in community residents' self-reported stress levels and engagement in more physical exercise than residents in control vacant lot areas. Other benefits included reductions in firearm assaults and vandalism (Branas et al., 2011).

## Teach Coping and Problem-Solving Skills

### Rationale

Building life skills prepares individuals to successfully tackle every day challenges and adapt to stress and adversity. Life skills encompasses many concepts, but most often include coping and problem-solving skills, conflict resolution, and critical thinking. Life skills are important in shielding individuals from suicidal behaviors (World Health Organization, 2014). Suicide prevention programs that focus on life and social skills training are drawn from social cognitive theories (Bandura, 1986), surmising that individuals who engage in suicidal behavior is attributed to either direct learning, modeling, and environmental and individual (e.g. hopelessness) characteristics. The literature linking life skills and suicide is robust--- The inability to employ adequate coping strategies to cope with immediate stressors or identify and find solutions for problems have been characterized among suicide attempters (Pollock & Williams, 2004). Treatments that include bolstering problem skills (Goldsmith, Pellmar, Kleinman, & Bunney, 2002) and include problem-solving techniques (Ghahramanlou-Holloway, Bhar, Brown, Olsen, & Beck, 2012; Townsend et al., 2001) appear to reduce suicidal ideation and attempts more effectively. Prevention programs focused on teaching these skills target youth, parents and families and have been used with both universal and at-risk populations. While many do not target suicidal behaviors directly, these programs strive to train youth and parents important life skills to offset the underlying vulnerabilities that contribute to engaging in high risk behaviors early in life.

### Approaches

Current evidence provides support for the following two approaches:

- **Social emotional learning programs** focus on developing and strengthening communication and problem-solving skills, emotion regulation, conflict resolution, help seeking and coping skills. These approaches address a range of risk and protective factors for suicidal behavior. They provide children and youth with skills to resolve problems in relationships, school, and with peers, and help youth to address other negative influences (e.g., substance use) associated with suicide. These approaches are typically delivered to all students in a particular grade or school, although some programs also focus on groups of students considered to be at high-risk for suicide. Opportunities to practice and reinforce skills are an important part of programs that work (Herman, Borden, Reinke, & Webster-Stratton, 2011).
- **Parenting skill and family relationship programs** are designed to strengthen parenting skills, enhance positive parent-child interactions, and improve children's behavioral and emotional skills and abilities. Several parenting and family relationship programs have been shown in rigorous evaluations to improve resilience and reduce risk factors for various behaviors,

including ones closely related to suicide, such as depression, internalizing behaviors, and substance abuse (M. S. Knox, Burkhart, & Hunter, 2010).

### Potential Outcomes

- Reduction in suicide attempts and suicide ideation
- Enhanced knowledge of risk and protective factors associated with suicide
- Reduction in suicide risk behaviors (i.e., depression, anxiety, conduct problems, substance abuse)
- Improve and normalize help-seeking behavior
- Enhance social competence and emotional regulation skills
- Enhance problem-solving and conflict management skills

### Evidence

There are several programs with evidence that support teaching social, emotional and parenting skills to reduce suicidal behaviors and associated risk factors.

- **Social emotional learning programs.** The *Youth Aware of Mental Health Program (YAM)* is a program developed for teenagers that uses interactive dialogue and role-playing to teach adolescents about the risk and protective factors associated with suicide (including knowledge about depression and anxiety) and enhances their problem-solving skills for dealing with adverse life events, stress, school and other problems. The program includes 3 hours of role-play sessions and interactive workshops combined with a booklet that students can keep, educational posters displayed in classroom, and interactive lectures about mental health at the beginning and end of the program (Wasserman et al., 2014). In a cluster-randomized controlled trial of YAM conducted across 10 European Union countries and 168 schools, students participating in the YAM program were significantly less likely to have an incident suicide attempt (OR 0.45, 95%CI 0.24–0.85;  $p=0.014$ ) and severe suicidal ideation (0.50, 0.27-0.92;  $p=0.025$ ) at the 12-month follow-up compared to the control group. Additionally, related to severe suicide ideation, in the YAM group absolute risk fell by 0.50% and RR fell by 49.6% (Wasserman et al., 2014).

*Signs of Suicide (SOS)* is another school-based prevention program for students aged 13-17. The program includes guided classroom discussions about suicide and depression. As part of the program, students are screened for depression and suicide risk and referred for professional help as indicated. The program is designed to increase knowledge about suicide and risk factors associated with suicidal behavior as well as improve and normalize help-seeking behavior (Schilling, Aseltine, & James, 2016). In a randomized controlled trial, SOS was shown to reduce self-reported suicide attempts at 3-months post intervention

among participating students compared to control students. The SOS program also increased students' knowledge of how to get help for themselves or friends for depression and/or suicidal thoughts, and favorable attitudes toward help-seeking. SOS participants with a lifetime history of suicide attempt were also less likely to report planning a suicide in the 3 months following the program compared to lower-risk participants (Schilling et al., 2016).

Finally, the *Good Behavior Game (GBG)* is a classroom-based program for elementary school children aged 6-10; it represents an example of upstream suicide prevention programming. The program uses a team-based behavior management strategy that promotes good behavior by setting clear expectations for good behavior and consequences for maladaptive behavior. The goal of the GBG is to create an integrated classroom social system that is supportive of all children being able to learn with little aggressive or disruptive behavior (Wilcox et al., 2008). In an outcome evaluation of the GBG, first graders assigned to GBG reported half the adjusted odds of suicidal ideation and suicide attempts. The beneficial effect of the program was consistent for suicidal ideation regardless of whether baseline covariates were included. The GBG effect on attempts was less robust in some adjusted models including caregiver mental health. In the second cohort of GBG students, neither suicidal ideation nor suicide attempts were significantly different between GBG and the control interventions (Wilcox et al., 2008). This finding likely arose due to the lack of implementation fidelity and pointed to the need for GBG to be delivered with precision, consistency, and teacher support. GBG was also found to be associated with reduced risk of later substance abuse, a risk factor for suicide (Kellam et al., 2008).

- **Parenting skill and family relationship programs.** Parenting and family skills training approaches have shown promising impacts in preventing key risk factors associated with suicide. For example, the *Incredible Years (IY)* is a comprehensive group training program for parents, teachers and children designed to reduce conduct and substance abuse problems, two important suicide risk factors, in youth by improving protective factors such as responsive and positive parent-teacher-child interactions and relationships, emotion self-regulation and social competence (all protective factors for suicide) (Herman et al., 2011). The program includes 9- 20 sessions offered in community-based settings (e.g., religious, recreation centers, mental health treatment centers, and hospitals). Several studies have demonstrated the effect of the IY program on reducing internalizing symptoms, such as anxiety and depression, and child conduct problems (C. H. Webster-Stratton, Reid, & Beauchaine, 2011; Webster-Stratton, Jamila Reid, & Stoolmiller, 2008). The program is also associated with improved problem-solving and conflict management; these skills were maintained at 1-year follow-up (Reid, Webster-Stratton, & Hammond, 2003; C. Webster-

Stratton & Hammond, 1997; C. Webster-Stratton, Reid, & Hammond, 2001). The program demonstrated greater benefits as the dosage of the intervention increased (Herman et al., 2011).

Additionally, *Strengthening Families 10-14* is a program that involves sessions between parents, youth, and family with the goal of improving parents' skills for disciplining, managing emotions and conflict, and communicating with their children; promoting youths' interpersonal and problem-solving skills; and creating family activities to build cohesion and positive parent-child interactions. The premise of the program is that developing these skills for both parents and children will reduce internalizing behavior and adolescent substance abuse, two important risk factors for suicide (Spoth, Gyll, & Day, 2002). *Strengthening Families* has been shown to decrease externalizing behaviors, alcohol use, and drug use among youth participants and reductions in depression, alcohol use, and drug use among participating families (Spoth et al., 2002).

## Identify and Support People At-Risk

### Rationale

In order to decrease suicide, attention to people at increased or high risk is necessary as these individuals tend to experience suicidal behavior at higher than average rates. These vulnerable or disadvantaged populations include, but are not limited to, individuals with lower socio-economic status or who are living with a mental health problem; people who have attempted suicide previously, individuals who are institutionalized, have been victims of violence, or are homeless; and members of certain ethnic minority groups. Supporting these vulnerable groups requires proactive case finding along with access to, and retention in, mental health services. Finding effective ways of identifying at-risk or vulnerable groups, customizing services to make them accessible and maintaining care remain key challenges. For example, simply improving services does not guarantee that those services will be used by those most in need of them, nor will it necessarily increase the number of people who follow treatments that are recommended. People who are disadvantaged face social and economic issues that may adversely affect their ability to respond to the treatments or advice that are offered.

### Approaches

The following three approaches focus on identifying and supporting people at increased risk.

- **Gatekeeper training** is designed to train teachers, coaches, providers and others in the community to identify people who may be at risk of suicide and to respond effectively, including facilitating treatment seeking and support services. Gatekeeper training is typically implemented in schools to identify at-risk youth and within health care settings to identify adults (and youth).
- **Screening combined with care management and overall continuity of care** has been used in primary care and behavioral health care settings to assure that people who may be at high-risk of suicide are identified and receive ongoing treatment as needed, particularly after inpatient discharge and other transitions within the healthcare system so they don't 'slip through the cracks'. These approaches typically employ screening for depression and/or suicide combined with collaborative treatment planning between patients and their providers and patient follow-up.
- **Crisis intervention.** These approaches provide support and referral services, typically by connecting a person in crisis (or a friend or family member of someone at-risk) to trained volunteers and/or professional staff via telephone hotline, online chat, or text messaging. Crisis intervention approaches are intended to impact key risk factors for suicide, including feelings of

depression, hopelessness, and subsequent mental health care utilization. Like means reduction, crisis interventions can put space or time between an individual who may be considering suicide and harmful behavior.

### Potential Outcomes

- Reduction in suicide attempts
- Reduction in suicide deaths
- Increased identification of individuals at-risk for suicidal behavior
- Increased at-risk individuals in treatment
- Increased community members trained to identify at-risk individuals
- Increased referrals for health care

### Evidence

There is evidence that community gatekeeper programs are successful in reducing suicides and suicide attempts but the efforts must be maintained (Substance Abuse and Mental Health Services Administration, 2014). However, there is limited evidence for effectiveness screening programs, but at the same time, standard principles for public health screening make them promising (Pena & Caine, 2006). The number of studies evaluating crisis intervention services is limited, but a few studies do indicate that those who use the hotline services have decreased suicidal thoughts and behavior.

- **Gatekeeper training.** *Mental Health First Aid (MHFA)* is a program designed for the lay public, which consists of three weekly sessions of three hours each. Participants learn the symptoms of people in mental health crises and/or in the early stages of mental health problems (i.e., those experiencing suicidal thoughts and behavior, acute stress reaction, panic attacks and acute psychotic behavior, and depression, anxiety, and psychotic disorders), possible risk factors, and where and how to get evidence-based effective help (Kitchener & Jorm, 2004). In a randomized controlled trial of 300 participants of *MHFA*, the intervention group reported greater confidence in providing help to others, greater likelihood of advising people to seek professional help, improved concordance with health professionals about treatments, and decreased stigmatizing attitudes. Additionally, the intervention resulted in improved mental health of the participants themselves. All results were statistically significant at  $p < .05$ . (Kitchener & Jorm, 2004). Additional research rigorously evaluating *MHFA* for its impact on the first aid recipients themselves and suicidal behavior is needed (Kitchener & Jorm, 2006).
- **Screening combined with care management and overall continuity of care.** The *Henry Ford Perfect Depression Care* program was the pre-cursor to *Zero Suicide*, and its overall goal was to

eliminate suicide. More broadly, though, the aim was to completely redesign depression care delivery to achieve breakthrough improvement in quality and safety by focusing on six aims: effectiveness, safety, patient centeredness, timeliness, efficiency, and equity among patients. The program developed concrete measures to assess progress on each of these aims and began with screening and assessment of each patient for suicide risk with coordinated continuous follow-up care system wide (C. E. Coffey, 2006). An examination of the impact of the *Henry Ford Perfect Depression Care (Pre-cursor to Zero Suicide)* program found that there was a dramatic and statistically significant decrease in the rate of suicide between the baseline years prior to the intervention (1999 and 2000) to the intervention years (2002-2009). During this time period, the suicide rate fell 82% (C. E. Coffey, 2006; C. E. Coffey, Coffey, & Ahmedani, 2013). Further, suicide rates also declined among HMO members who participated in targeted suicide prevention efforts and received mental health specialty services. However, for those HMO members who accessed only general medical services as opposed to specialty mental health services, the suicide rate increased (M. Coffey, Coffey, & Ahmedani, 2015).

- **Crisis intervention.** In an evaluation of the effectiveness of the National Suicide Prevention Lifeline (NSPL) to prevent suicide, 1,085 suicidal individuals who called the hotline completed a standard risk assessment for suicide, and 380 of those completed a follow-up assessment between 1 and 52 days after the initial assessment. Researchers found that over half of the initial sample were seriously considering suicide when they called, and they had a plan for their suicide. Researchers also found that participants experienced significant decreases in suicidality over the course of the telephone session, and that levels of hopelessness and psychological pain continued to decrease after their initial call (Gould, Kalafat, Harrismunfakh, & Kleinman, 2007).

In another study, this time employing a randomized controlled trial, Gould, Cross, Pisani, Munfakh, and Kleinman (2013) assessed the impact of the *Applied Suicide Intervention Skills Training (ASIST)*, a widely implemented gatekeeper training program that helps hotline counselors, emergency workers, and other gatekeepers to identify and connect with suicidal individuals, understand their reasoning for living and dying, and assist with safely connecting those in need to available resources. The training was evaluated across the NSPL network of hotlines over the period 2008-2009. Using data from 1,410 suicidal individuals who called 17 Lifeline centers, researchers found that compared to callers who spoke to counselors that received the usual care training, individuals who spoke with counselors trained in ASIST were significantly more likely to feel less depressed, less suicidal, less overwhelmed, and more hopeful by the end of their call to the hotline. Counselors trained in ASIST were also more skilled at keeping callers on the phone longer and establishing a connection with them.

However, training in ASIST did not result in more comprehensive suicide risk assessments than usual care training (Gould et al., 2013).

## Intervene to Lessen Harms and Prevent Future Risk

### Rationale

Individuals who have experienced mental health challenges, suicidal ideation, and/or who have made suicide attempts and/or have engaged in non-suicidal self-injury are at increased risk of suicide (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012). Risk of suicide can also increase among those who have lost a friend, family member, co-worker, or other acquaintance to suicide (Pitman, Osborn, King, & Erlangsen, 2014). Exposure to sensationalized or uninformed reporting regarding on suicide may heighten the risk of suicide among vulnerable individuals and can inadvertently contribute to suicide contagion (Etzersdorfer & Sonneck, 1998; Niederkrotenthaler & Sonneck, 2007).

### Approaches

A broad array of approaches to lessen harms and reduce future risk of suicide among those at increased risk include the provision of mental health care and improved continuity of care, improving linkage to care through active post-discharge planning and follow-up that decreases barriers to ongoing therapeutic support, increasing connectedness to supportive others, addressing bereavement, and framing communications to emphasize resilience, decrease negative affect, and to prevent contagion.

- **Treatment for people at-risk of suicide** typically includes various forms of psychotherapy delivered by licensed providers to help individuals with mental health problems and other risk factors for suicide with problem-solving, impulsivity and emotion regulation.
- **Treatment to prevent re-attempts.** These approaches typically include follow-up contact and use diverse modalities (e.g., home visits, mail, telephone, e-mail) to engage recent suicide attempt survivors in continued treatment to prevent re-attempts. Treatment may focus on improved coping skills, mindfulness, and other emotional regulation skills, and may include case management home visits to increase adherence to treatment and continuity of care; and one-on-one interpersonal therapy and/or group therapy. Approaches that engage and connect attempters to peers and providers are especially important because many attempters do not present to aftercare; 12%-25% reattempt within a year, and 3%-9% of attempt survivors die by suicide within 1 to 5 years of their initial attempt (Inagaki et al., 2015)
- **Postvention** approaches are implemented *after* a suicide has taken place and may include debriefing sessions, counseling, and/or bereavement support groups for surviving friends and family members/loved ones. These programs have not typically been evaluated for their impact on suicide or suicidal behavior but may reduce survivors' guilt, feelings of depression, and complicated grief (Szumilas & Kutcher, 2011).

- **Safe messaging following a suicide.** The manner in which information on a recent suicide is communicated to the public (e.g. school assemblies, mass media, social media) can heighten the risk of suicide among vulnerable individuals and can inadvertently contribute to suicide contagion. Therefore, responsible and safe reporting may help prevent suicide and/or suicide contagion.

### Potential Outcomes

- Reduction in mental health-related sequelae
- Increase connectedness
- Improved coping skills
- Improved messaging following suicide
- Reduction in re-attempts

### Evidence

The evidence addressing strategies to lesson harm and prevent future risk of suicide includes the evaluation of effects of specific approaches on risk and protective factors as well as suicide-related mortality. However, because the evaluation of suicide-related mortality requires large sample sizes and extended follow-up, much of the evidence in this area primarily focuses on risk and protective factors.

- **Treatment for people at-risk of suicide.**

**Improving Mood – Promoting Access to Collaborative Treatment (IMPACT)** is a program that aims to prevent suicide among older primary care patients by reducing suicide ideation and depression in primary care settings. IMPACT facilitates the development of a therapeutic alliance, a personalized treatment plan that includes patient preferences, as well as proactive follow-up (biweekly during an acute phase and monthly during continuation phase) by a depression care manager (Hunkeler et al., 2006). The program has been shown to significantly improve quality of life, and to reduce functional impairment, depression and suicidal ideation over 24-months of follow-up (Hunkeler et al., 2006; Unutzer et al., 2006) relative to patients who received care as usual.

**Collaborative Assessment and Management of Suicidality (CAMS)** is a therapeutic framework for suicide-specific assessment and treatment of patient's suicide risk. This flexible approach can be used across treatment settings and clinician theoretical orientations and involves the clinician and patient working together in an interactive assessment process to develop patient-

specific treatment plans. CAMS sessions are collaborative and involve constant patient about what is and is not working with the ultimate goal of enhancing the therapeutic alliance and increasing treatment motivation in the suicidal patient. CAMS been tested and supported in 6 correlational studies (Jobes, 2012), in a variety of inpatient and outpatient settings and in one RCT with several additional RCTs under way. CAMS has been associated with significant improvements in suicidal ideation, overall symptom distress, and feelings of hopelessness at 12 month follow-up among a community-based sample of suicidal outpatients. (Comtois et al., 2011).

**Dialectical Behavioral Therapy (DBT)** is a multicomponent therapy for individuals at high risk for suicide and who may struggle with impulsivity and emotional regulation. The components of DBT include individual therapy, group skills training, between-session telephone coaching and a therapist consultation team. In a randomized controlled trial of women with recent suicidal or self-injurious behavior, those receiving DBT were half as likely to make a suicide attempt at two-year follow-up than women receiving community treatment (23% vs 46%), required less hospitalization for suicide ideation, and had lower medical risk across all suicide attempts and self-injurious acts combined (Linehan et al., 2006).

**Attachment-Based Family Therapy (ABFT)** is a program for adolescents aged 12-18 and is designed to treat clinically diagnosed major depressive disorder, eliminate suicidal ideation, and reduce dispositional anxiety (Diamond et al., 2010). A randomized controlled trial of ABFT found that suicidal adolescents assigned to ABFT experienced significantly greater improvement in suicidal ideation over 24 weeks of follow-up than did adolescents assigned to enhanced usual care (-4.37 vs. -2.34;  $p = .001$ ;  $d=0.97$ ). Additionally, a higher percentage of ABFT participants reported no suicidal ideation in the week prior to assessment at 12 weeks than did adolescents receiving enhanced usual care (69.2% vs. 34.6%;  $p = .01$ ; OR= 4.25) and at 24 weeks (82.1% vs. 46.2%;  $p = .006$ ; OR=5.37) (Diamond et al., 2010).

- **Treatment to prevent re-attempts.**

**Emergency Department Brief Intervention with Follow-up Visits** is a program that involves a one-hour discharge information session that addresses suicidal behavior, distress, risk and protective factors, alternatives to suicidal behavior, and referral options, combined with nine follow-up contacts over 18-months (at 1, 2, 4, 7, 11 weeks and 4, 6, 12, 18 months). Follow-up contacts are either conducted by phone or through home visits according to a specific time line for up to 18-months. A randomized controlled trial that enrolled suicide attempters from eight hospital emergency departments in five culturally different sites found that a brief intervention combined with 9 follow-up visits over 18-months was associated with significantly fewer deaths

from suicide relative to a treatment-as-usual group (0.2% versus 2.2%, respectively;  $\chi^2 = 13.83$ ,  $P < 0.001$ ) (Fleischmann et al., 2008).

**Active follow-up contact approaches** such as postcards, letters, and telephone calls, are intended to increase a patient's sense of connectedness with health care providers and decrease isolation. These approaches include expression of care and support and typically invite patients to reconnect with their provider. Contacts are made periodically (e.g., monthly or every few months in the first 12 months post-discharge with some programs continuing contact for 2 or more years). These approaches have been found in a meta-analysis conducted by Inagaki et al. (2015) to reduce reattempts by approximately 17% for up to 12 months post-discharge, however, the long-term effects of these approaches on reattempts has not yet been demonstrated. Also, because the number of trials and associated sample sizes included in this meta-analysis were small, it was not possible to determine the effect of active contact and follow-up approaches on death by suicide. In a randomized controlled trial of post-crisis suicide prevention long-term follow-up contact approach, Motto and Bostrom (2001) found that patients who refused ongoing care but who were randomized to be contacted by letter four times per year had a lower rate of suicide over two years of follow-up than did patients in the control group who received no further contact. Other studies have also shown post-crisis letters and coping cards to be protective against suicide ideation and attempts (Hassanian-Moghaddam, Sarjami, Kolahi, & Carter, 2011; Wang et al., 2016).

**Cognitive Behavior Therapy for Suicide Prevention (CBT-SP)** is a strategy that uses a risk reduction, relapse prevention approach that includes an analysis of proximal risk factors and stressors (e.g., relationship problems, school or work-related difficulties) leading up to and following the suicidal event; safety plan development; skill building; and psychoeducation. *CBT-SP* also has family skill modules focused on family support and communication patterns as well as improving the family's problem solving skills. A randomized controlled trial found of *CBT-SP* found that 10-session outpatient cognitive therapy designed to prevent repeat suicide attempts resulted in a 50% reduction in the likelihood of a suicide reattempt among adults who had been admitted to an emergency department for a suicide attempt relative to treatment as usual (Brown et al., 2005).

- **Postvention** programs such as *StandBy Response Service* are implemented with the goal of providing support to survivors of suicide. *StandBy* provides clients with face-to-face outreach and telephone support through a professional crisis response team. Site coordinators develop customized case management plans, referring clients to other existing community services matched to their needs (Visser, Comans, & Scuffham, 2014). In a study by Visser et al. (2014), *StandBy* clients were significantly less likely to be at high risk for suicidality than a suicide bereaved comparison group who had not had contact with the *StandBy* program (48% and 64%

respectively,  $p = 0.005$ ). Additionally, research suggests that active postvention approaches in which outreach to suicide survivors occurs at the scene of a suicide is associated with intake into treatment sooner, greater attendance at support group meetings, and attendance at more meetings compared to passive postvention (versus passive approaches where survivors self-refer for services) (J. Cerel & Campbell, 2008).

- **Safe messaging following a suicide.** *Media guidelines* for reporting on suicides can help assure that stories on suicide are communicated in a safe and effective way. Reports that are both inclusive of suicide prevention messages, stories of hope and resilience, risk and protective factors, and links to helping resources (e.g., hotline) and that avoid sensationalizing events or reducing suicide to one cause can help reduce the likelihood of suicide contagion. The most compelling evidence supporting the effect of *media guidelines* on reduction in suicides comes from Austria. After a sharp increase in suicides on the Viennese subway, media guidelines were introduced and an interrupted time series design was used to evaluate the national impact of the guidelines on subsequent suicides. Changes in the quality and quantity of media reporting resulted in a reduction of 81 suicides annually (95% confidence interval: -149 to -13;  $t = -2.32$ ,  $df = 54$ ,  $p < 0.024$ ) in the Viennese subway system (Niederkrotenthaler & Sonneck, 2007)

## Sector Involvement

Public health can play an important and unique role in addressing suicide. Public health agencies, which typically place prevention at the forefront of efforts and work to create broad population-level impact, can bring critical leadership and resources to bear on this problem. For example, these agencies can serve as a convener, bringing together partners and stakeholders to plan, prioritize, and coordinate suicide prevention efforts. Public health agencies are also well positioned to collect and disseminate data, implement preventive measures, evaluate programs, and track progress. Although public health can play a leadership role in preventing suicide, the strategies and approaches outlined in this technical package cannot be accomplished by the public health sector alone.

Other sectors vital to implementing this package include, but are not limited to, education, government (local, state, and federal), social services, health services, business/labor, justice, housing, media, and organizations that comprise the civil society sector such as faith-based organizations, youth-serving organizations, foundations, and other non-governmental organizations. Collectively, these sectors can make a difference in preventing suicide by impacting the various contexts and underlying risks that contribute to suicide.

The strategies and approaches described in this technical package are summarized in Appendix A along with the relevant sectors that are well positioned to lead implementation efforts.

[I can write the text specific to the strategies and approaches. I've done this for the other TPs and am happy to do the same here. This is the section where we distinguish the strategies where public health is best positioned to lead from those where leadership is necessary from other sectors and how public health can assist, etc.]

Regardless of strategy, action by many sectors will be necessary for the successful implementation of this package. In this regard, all sectors can play an important and influential role in creating safe and protective environments where individuals who are at high risk of suicide can easily access the mental healthcare and services they need.

## Monitoring and Evaluation

Monitoring and evaluation are necessary components of the public health approach to prevention. It is important to have timely and reliable data to monitor the extent of the problem and to evaluate the impact of prevention efforts. Data are necessary for program implementation; planning, implementation, and assessment all rely on accurate measurement of the problem.

Surveillance data helps researchers and practitioners track changes in the burden of suicide.

Surveillance systems exist at the federal, state, and local levels. It is important to assess the availability of surveillance data and data systems across these levels to identify and address gaps in the systems. CDC's National Vital Statistics System and the National Violent Death Reporting System (NVDRS) are examples of surveillance systems that provide data on deaths from suicide. NVDRS, for example, is a state-based surveillance system that combines data from death certificates, law enforcement reports, and coroner or medical examiner reports to provide detailed information on the circumstances of violent deaths, including suicide, which can assist communities in guiding prevention approaches (Blair, Fowler, Jack, & Crosby, 2016). The National Electronic Injury Surveillance System-All Injury Program (NEISS-AIP) provides nationally representative data about all types and causes of nonfatal injuries treated in U.S. hospital emergency departments, and can be used to assess national rates of, and trends in, self-harm injuries by cause (e.g., falls, poisoning, etc.), age, race/ethnicity, sex, disposition (where the injured person goes when released from the Emergency Department (<http://www.cdc.gov/injury/wisqars/nonfatal.html>)).

In addition to information on deaths and nonfatal injuries, there are also surveillance systems that provide national, state, and some local estimates of suicidal behavior. The Youth Risk Behavior Surveillance System (YRBSS) collects information from a nationally representative sample of 9-12 grade students and is a key resource in monitoring health-risk behaviors among youth, including whether youth have seriously considered attempting suicide, attempted suicide, made a plan, or required treatment by a doctor or nurse for a suicide attempt that resulted in an injury, poisoning, or overdose (Brener et al., 2013). The YRBSS data are obtained from a national school-based survey conducted by CDC as well as school-based state, territorial, tribal, and large urban school district survey conducted by education and health agencies. The National Survey on Drug Use and Health (NSDUH) is an annual nationwide survey of individuals aged 12 years and older that provides national and state-level estimates of drug use and mental health-related issues, including suicide ideation and suicide attempts (<https://nsduhweb.rti.org/respweb/homepage.cfm>).

It is also important at all levels (local, state, and federal) to address gaps in responses, track progress of prevention efforts and evaluate the impact of those efforts, including the impact of this technical package. Evaluation data, produced through program implementation and monitoring, is essential to provide information on what does and does not work to reduce rates of suicide and its associated risk

and protective factors. Theories of change and logic models that identify short, intermediate, and long-term outcomes are an important part of program evaluation.

The evidence-base for suicide prevention has advanced greatly over the last few decades. However, additional research is needed to understand the impact of prevention programs on preventing suicide, as opposed to merely examining the effectiveness of programs to impact risk factors associated with suicide. More research is also needed to examine the effectiveness of upstream and community-level strategies to prevent suicide at the population level. Lastly, it will be important for researchers to test the effectiveness of combinations of the strategies and approaches included in this package. Most existing evaluations focus on approaches implemented in isolation. However, there is potential to understand the synergistic effects within a comprehensive prevention approach. Additional research is needed to understand the extent to which combinations of strategies and approaches result in greater reductions in suicide than individual programs, practices, or policies.

## Conclusion

Suicide is a serious public health problem whose rates have been on the rise for more than a decade and whose costs stretch well into the billions of dollars each year. And while suicide is a rare outcome statistically, its human impact has a ripple effect that is far-reaching. Each of us likely interacts with suicide survivors, those with lived experience, and those with thoughts of suicide, on a daily basis—at home, at work, and in our communities. Suicide and suicide attempts are therefore public health issues of societal concern. Fortunately, like many public health problems, suicide is preventable, and fortunately more is being done to prevent suicide than ever before, as evidenced by the work of the National Action Alliance for Suicide Prevention, the release of the first world report on suicide, more timely surveillance data, and critical mention in the President’s FY17 budget, to name just a few examples. Unfortunately and unlike most other public health problems, suicide still struggles against stigma, shame, and secrecy related to help-seeking, mental illness, being a survivor, or someone with lived experience; misplaced fear of asking someone about their risk of suicide (versus the fear and consequence of not asking), and fear of taking up certain strategies known to be effective but perhaps unpopular; misinformation about suicide preventability, and disproportionate funding given the public health burden. Suicide also struggles against the right degree of awareness where too much information, for example by well-meaning reporters and others, may actually do harm.

In an effort to continue pushing the field and society further towards prevention, this technical package includes strategies and approaches that ideally would be used in a comprehensive fashion, in combination—in a multi-level, multi-sectoral way. This technical package includes strategies and approaches targeting upstream prevention, e.g., social emotional learning for children and youth, as well as strategies focused more downstream, e.g., cognitive behavioral treatment to prevent re-

attempts. It includes universal, selective, and indicated strategies, or strategies that focus on the whole population regardless of risk to strategies that focus on those groups at highest risk. Importantly, this technical package extends the bounds of the typical prevention strategies to consider approaches at the outer levels of the social ecology, e.g., policies to stabilize housing and community engagement initiatives. In short, care and attention has been paid to all aspects of suicide prevention.

While the evidence base continues to be built, the collection of programs, policies, and practices laid out here are available for implementation now. And in keeping with good public health practice, the intent is that monitoring and evaluation will play a key role in that implementation. Moreover, as new evidence becomes available, this technical package can be refined to reflect the current state of the science.

In closing, and in keeping with a message of resilience as spoken by those with lived experience, ‘hope, help, and healing is possible.’

## Appendix A: Summary of Strategies and Approaches to Prevent Suicide

Strategy	Approach/Program, Practice or Policy	Best Available Evidence			Lead Sectors <sup>1</sup>
		Suicide	Suicide Attempts or Ideation	Other Risk/Protective Factors for Suicide	
Strengthen economic supports	Strengthen financial security				
	Unemployment benefit programs	X			Government (local, state, Federal)
	Housing stabilization policies				
	The National Neighborhood Stabilization Program			X	Government (local, state, Federal)
Strengthen access to mental health care	Coverage of mental health conditions in health insurance policies				
	Mental Health Parity Laws	X		X	Healthcare  Government (local, state, Federal)
Establish protective environments	Means restriction				
	Intervening at hot spots	X			Government (local, state, Federal)
	Safe storage practices		X (attempts)	X (Safe storage of firearms and medication)	Government (local, state, Federal)
	Organizational policies and culture				

		Best Available Evidence			
	<i>Together for Life</i>	X			Business/Labor
	<i>US Air Force Suicide Prevention Program</i>	X		X (family violence)	Government (local, state, Federal)  Business/Labor
	Community-based policies to reduce excessive alcohol use				
	<i>Alcohol outlet density</i>	X		X	Government (local, state, Federal)
Promote connectedness to protect against suicide	Peer norm approaches				
	<i>Sources of Strength</i>			X	Public Health Social Services
	Community-engagement activities				
	<i>Greening vacant urban spaces</i>			X	Public Health
Teach coping and problem-solving skills	Social emotional learning				
	<i>Youth Aware of Mental Health Program</i>		X		Public Health Social Services
	<i>Signs of Suicide</i>		X	X	
	<i>Good Behavior Game</i>		X	X	
	Parenting skill and family relationship approaches				
	<i>The Incredible Years</i>			X	Public Health Social Services

		Best Available Evidence			
	Strengthening Families 10-14			X	
Identify and support people at-risk	Gatekeeper training				
	Mental Health First Aid			X	Public Health Healthcare Social Services
	Screening combined with care management				
	Henry Ford Perfect Depression Care (Pre-cursor to Zero Suicide)	X		X	Healthcare
	Crisis Intervention				
	National Suicide Prevention Lifeline		X	X	Public Health Social Services
	Applied Suicide Intervention Skills Training		X	X	
Intervene to lessen harms and prevent future risk	Treatment for people at risk of suicide				
	Improving Mood – Promoting Access to Collaborative Treatment (IMPACT)		X	X	Healthcare Social Services
	Collaborative Assessment and Management of Suicidality (CAMS)		X	X	
	Dialectical Behavioral Therapy		X	X	
	Attachment-Based Family Therapy		X		
	Treatment to prevent re-attempts				

		Best Available Evidence			
	<i>ED Brief Intervention with Follow-up Visits</i>	X			Healthcare
	<i>Active follow-up contact approaches</i>	X	X		
	<i>CBT for Suicide Prevention</i>				
	Postvention				
	<i>StandBy Response Service</i>		X		Healthcare
	Safe messaging following a suicide				
	<i>Media Guidelines</i>	X			Public Health

<sup>1</sup>This column refers to the lead sectors well positioned to bring leadership and resources to implementation efforts. For each strategy, there are many other sectors such as non-governmental organizations that are instrumental to prevention planning and implementing the specific programmatic activities.

## Overview

This technical package represents a select group of strategies based on the best available evidence to help communities and states sharpen their focus on prevention activities with the greatest potential to prevent suicide. These strategies include strengthening economic supports; strengthening access to mental health care; creating protective environments; promoting connectedness to protect against suicide; teaching coping and problem-solving skills; identifying and supporting people at-risk; and intervening to lessen harms and prevent future risk. The strategies represented in this package include those with a focus on preventing suicide from happening in the first place as well as approaches to lessen the immediate and long-term harms of suicidal behavior for individuals, families, communities, and society. The strategies in the technical package support the goals and objectives of the National Strategy for Suicide Prevention and the National Action Alliance for Suicide Prevention's priority to strengthen community-based prevention. Commitment, cooperation, and leadership from numerous sectors, including public health, education, justice, health care, social services, business/labor, and government can bring about the successful implementation of this package.

### What is a Technical Package?

A technical package is a compilation of a core set of strategies to achieve and sustain substantial reductions in a specific risk factor or outcome (Frieden, 2014). Technical packages help communities and states prioritize prevention activities based on the best available evidence. This technical package has three components. The first component is the **strategy** or the preventive direction or actions to achieve the goal of preventing suicide. The second component is the **approach**. The approach includes the specific ways to advance the strategy. This can be accomplished through *programs, policies, and practices*. The approaches included come primarily from studies based in the United States. The **evidence** for each of the approaches in preventing suicide or its associated risk factors is included as the third component. This package is intended as a resource to guide and inform prevention decision-making in communities and states.

### Preventing Suicide is a Priority

Suicide, as defined by the Centers for Disease Control and Prevention (CDC), is part of a broader class of behavior called *self-directed violence*. Self-directed violence refers to behavior directed at oneself that deliberately results in injury or the *potential* for injury (Crosby, Ortega, & Melanson, 2011). Self-directed violence may be *suicidal* or *non-suicidal* in nature. For the purposes of this document, we refer only to behavior where suicide is intended:

- **Suicide** is a death caused by self-directed injurious behavior with any intent to die as a result of the behavior.

- **Suicide attempt** is defined as a *non-fatal* self-directed and potentially injurious behavior with any intent to die as a result of the behavior. A suicide attempt may or may not result in injury.

**Suicide is highly prevalent.** Suicide presents a major challenge to public health in the United States and worldwide. It contributes to premature death, morbidity, lost productivity, and health care costs (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014). In 2014 (the most recent year of available death data), suicide was responsible for 42,773 deaths in the U.S., which is approximately one suicide every 12 minutes (Centers for Disease Control and Prevention, 2016d). In 2014, suicide ranked as the 10th leading cause of death and has been among the top 12 leading causes of death since 1975 in the U.S (Centers for Disease Control and Prevention, 2016d). Overall suicide rates have increased 24% from 1999 to 2014 (Curtin, Warner, & Hedegaard, 2016). Suicide is a problem throughout the life span; it is the second leading cause of death among those aged 10–19 years, also second among persons in their 20s and 30s; it is the fourth leading cause among persons in their 40s and seventh among persons in their 50s (Centers for Disease Control and Prevention, 2016d).

Suicides reflect only a portion of the problem (Crosby, Han, Ortega, Parks, & Gfroerer, 2011). Substantially more people are hospitalized as a result of nonfatal suicidal behavior (i.e. suicide attempts) than are fatally injured, and an even greater number are either treated in ambulatory settings (e.g., emergency departments) or not treated at all (Crosby, Han, et al., 2011). For example, during 2014, among adults aged 18 years and older, for every one suicide there were 9 adults treated in hospital emergency departments for self-harm injuries, 27 who reported making a suicide attempt, and over 227 who reported seriously considering suicide (i.e. ideation) (Ferdon et al., In press).

**Suicide is associated with several risk and protective factors.** Suicide, like other human behaviors, is complex with no single determining cause. Instead, suicide occurs in response to multiple biological, psychological, interpersonal, environmental and societal influences that interact with one another, often over time. The social-ecological model-- encompassing multiple levels of focus from the individual, relationship, community, and societal-- is a useful framework for viewing and understanding suicide risk factors identified in the literature (Dahlberg & Krug, 2002). Risk and protective factors for suicide exist at each level. For example, risk factors include:

- **Individual level:** History of depression and other mental illnesses, alcohol and drug abuse, previous suicide attempt, violence victimization, genetic and biological determinants, hopelessness
- **Relationship level:** High conflict or violent relationships, sense of isolation and lack of social support, family/loved one's history of suicide, financial and work stress
- **Community level:** Inadequate community connectedness, barriers to health care (e.g., lack of access to providers and medications)

- **Societal level:** Availability of lethal means of suicide, unsafe media portrayals of suicide, stigma associated with help-seeking and mental illness (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014).

It is important to recognize that the vast majority of individuals who are depressed or who have other risk factors noted, do *not* die by suicide. Furthermore, the relevance of each risk factor can vary by age, race, gender, sexual orientation, residential geography, and socio-cultural and economic status (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014).

Protective factors, or those influences that guard *against* the risk for suicide, can also be found across the different levels of the social-ecological model. Protective factors identified in the literature include: effective coping and problem solving skills, moral objections to suicide, strong and supportive relationships with partners, friends, and family; connectedness to school, community and other social institutions; availability of quality and ongoing physical and mental health care, and reduced access to lethal means (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014). These protective factors can either counter a specific risk factor or guard against a number of risks associated with suicide.

**Suicide is connected to other forms of violence.** Suicide and other forms of violence often share some of the same root causes (Butchart, Phinney, Check, & Villaveces, 2004; Klevens, Simon, & Chen, 2012). For example, in neighborhoods where there is low social cohesion, or where residents don't support and trust each other, people are at higher risk for suicide (Desai, Dausey, & Rosenheck, 2005) as well as perpetration of child maltreatment (Coulton, Crampton, Irwin, Spilsbury, & Korbin, 2007; Freisthler, Merritt, & LaScala, 2006), teen dating violence (Capaldi, Noble, Shortt, & Kim, 2012), intimate partner violence (Pinchevsky & Wright, 2012), and youth violence (Sampson, Morenoff, & Gannon-Rowley, 2002). Additionally, a lack of economic opportunities and unemployment are associated with suicide (Luo, Florence, Quispe-Agnoli, Ouyang, & Crosby, 2011; Reeves et al., 2012), as well as perpetration of child maltreatment (D. Runyan, Wattam, Ikeda, Hassan, & Ramiro, 2002), intimate partner violence (Heise & Garcia-Moreno, 2002; Pinchevsky & Wright, 2012), sexual violence (Centers for Disease Control and Prevention, 2016c) and youth violence (Wilson, 2011). Other shared risk factors for suicide and violence occur at the individual level and include substance abuse, mental health problems, witnessing violence, and a lack of problem-solving skills (Centers for Disease Control and Prevention, 2016a, 2016c, 2016e; U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012).

Just as risk factors may be shared across suicide and violence, so too may protective factors overlap. For example, connectedness increases individual's and communities' resilience to suicide and other forms of violence, including connectedness to one's community (Basile, Hamburger, Swahn, & Choi, 2013; Borowsky, Hogan, & Ireland, 1997; Centers for Disease Control and Prevention, 2016b; Coulton et al.,

2007; Kleiman, Riskind, Schaefer, & Weingarden, 2012; Pinchevsky & Wright, 2012; Widome, Sieving, Harpin, & Hearst, 2008), school (Basile, Espelage, Rivers, McMahon, & Simon, 2009; Capaldi et al., 2012; Carter, McGee, Taylor, & Williams, 2007; DeGue et al., 2013; Hong, Kral, Espelage, & Allen-Meares, 2012; Losel & Farrington, 2012), family (Capaldi et al., 2012; Centers for Disease Control and Prevention, 2016a; Elgar, Craig, Boyce, Morgan, & Vella-Zarb, 2009; Maimon, Browning, & Brooks-Gunn, 2010; Resnick, Ireland, & Borowsky, 2004), caring adults (Capaldi et al., 2012; Losel & Farrington, 2012; Maimon et al., 2010), and pro-social peers (Capaldi et al., 2012; Losel & Farrington, 2012).

**The health and economic consequences of suicide are substantial.** Suicide and suicide attempts have far-reaching consequences for individuals, families, and communities (Dunne, McIntosh, & Dunne-Maxim, 1987; Mishara, 1995; National Action Alliance for Suicide Prevention: Suicide Attempt Survivors Task Force, 2014; National Action Alliance for Suicide Prevention: Survivors of Suicide Loss Task Force, 2015). By one conservative estimate, for every death by suicide six people are directly impacted (i.e. survivors). Based on this figure it is estimated that there are over 13 million survivors in the U.S. and unfortunately, survivorship itself is a risk factor for suicide (Crosby & Sacks, 2002). Research indicates that the health consequences of violence, including suicide, are also much more extensive than injury and death. Suicide attempt survivors (i.e. those with lived experience) may suffer long-term health and mental health consequences ranging from anger, guilt, and physical impairment, depending on the means and severity of the attempt (Chapman & Dixon-Gordon, 2007). Similarly, survivors of a loved one's suicide may experience ongoing pain and suffering including complicated grief (Mitchell, Kim, Prigerson, & Mortimer-Stephens, 2004), stigma, depression, anxiety, post-traumatic stress disorder, and increased risk of suicidal ideation and suicide (Julie Cerel, McIntosh, Neimeyer, Maple, & Marshall, 2014; Sudak, Maxim, & Carpenter, 2008).

The economic toll of suicide is immense as well. The total lifetime costs associated with nonfatal injuries and deaths caused by self-directed violence in 2013 were approximately \$93.5 billion after adjusting for under-reporting of suicide (Shepard, Gurewich, Lwin, Reed, & Silverman, 2016). The overwhelming burden of these costs results from lost productivity over the life course, with the average cost per suicide being over \$1.3 million (Shepard et al., 2016).

**Suicide can be prevented.** Despite the myths surrounding suicide, like most public health problems, suicide is preventable (U.S. Public Health Service, 1999). And while progress will continue to be made into the future, evidence for numerous programs, practices, and policies currently exists, and many programs are ready to be implemented now. Just as suicide is not caused by a single factor, research suggests that suicide will not be prevented by any single intervention taking place in any single setting (Silverman & Maris, 1995; U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012). Rather, suicide prevention is best achieved by a focus across the individual-, relationship-, family-, community, and societal-levels and across all sectors, private and public (e.g.,

business, public health, physical and behavioral healthcare, justice, education, labor) (National Action Alliance for Suicide Prevention, 2014; World Health Organization, 2014).

### **Assessing the Evidence**

This technical package includes programs, practices, and policies with evidence of impact on suicide or risk or protective factors for suicide. To be considered for inclusion in the technical package, the program, practice, or policy selected had to meet at least one of these criteria: a) meta-analyses or systematic reviews showing impact on suicide; b) evidence from at least one rigorous (e.g., randomized controlled trial [RCT] or quasi-experimental design) evaluation study that found significant preventive effects on suicide; c) meta-analyses or systematic reviews showing impact on risk or protective factors for suicide, or d) evidence from at least one rigorous (e.g., RCT or quasi-experimental design) evaluation study that found significant impacts on risk or protective factors for suicide. Finally, consideration was also given to the likelihood of achieving beneficial effects on multiple forms of violence; no evidence of harmful effects on specific outcomes or with particular subgroups; and feasibility of implementation in a U.S. context if the program, policy, or practice has been evaluated in another country.

Within this technical package, some approaches do not yet have research evidence demonstrating impact on rates of suicide but instead are supported by evidence indicating impacts on risk or protective factors for suicide (e.g., help-seeking, stigma reduction, depression, connectedness). In terms of the strength of the evidence, programs that have demonstrated effects on suicidal behavior (e.g., reductions in deaths, attempts) provide a higher-level of evidence, but the evidence base is not that strong in all areas. For instance, there has been less evaluation of community engagement and family programs on suicidal behavior. Thus, approaches in this package that have effects on risk or protective factors reflect the developmental nature of the evidence base and the use of the best available evidence at a given time.

It is also important to note that there is often significant heterogeneity among the programs, policies, or practices that fall within one approach or strategy area in terms of the nature and quality of the available evidence. Not all programs, policies, or practices that utilize the same approach (e.g., gatekeeper training) are equally effective, and even those that are effective may not work across all populations. Tailoring programs and more evaluation may be necessary to address different population groups. The examples provided are not intended to be a comprehensive list of evidence-based programs, policies, or practices for each approach, but rather illustrate models that have been shown to impact suicide or have beneficial effects on risk or protective factors for suicide. In practice, the effectiveness of the programs, policies and practices identified in this package will be strongly dependent on the quality of their implementation and the communities in which they are implemented. Implementation guidance to assist practitioners, organizations and communities will be developed separately.

### Context and Cross-Cutting Themes

The strategies and approaches that have been included in this technical package represent different levels of the social ecology, with efforts intended to impact the community and societal levels, as well individual and relationship levels. The strategies and approaches are intended to work in combination and reinforce each other to prevent suicide (see box below). The strategies are arranged in order such that those strategies hypothesized to have the greatest potential for broad public health impact on suicide are included first, followed by those that might impact more select populations (e.g., persons who have already made a suicide attempt).

**Comment [A]:** Can we just call this Promote Connectedness so it's more consistent with other strategy titles? Not sure why we have to say to protect against suicide.

Preventing Suicide	
Strategy	Approach
Strengthen economic supports	<ul style="list-style-type: none"><li>Strengthen household financial security</li><li>Housing stabilization policies</li></ul>
Strengthen access to mental health care	<ul style="list-style-type: none"><li>Coverage of mental health conditions in health insurance policies</li></ul>
Create protective environments	<ul style="list-style-type: none"><li>Reducing access to lethal means among persons at-risk of suicide</li><li>Organizational policies and culture</li><li>Community-based policies to reduce excessive alcohol use</li></ul>
Promote connectedness to protect against suicide	<ul style="list-style-type: none"><li>Peer norm approaches</li><li>Community engagement activities</li></ul>
Teach coping and problem-solving skills	<ul style="list-style-type: none"><li>Social-emotional learning</li><li>Parenting skill and family relationship approaches</li></ul>
Identify and support people at risk	<ul style="list-style-type: none"><li>Gatekeeper training</li><li>Screening combined with care management</li><li>Crisis intervention</li></ul>
Intervene to lessen harms and prevent future risk	<ul style="list-style-type: none"><li>Treatment for people at-risk of suicide</li><li>Treatment to prevent re-attempts</li><li>Postvention</li><li>Safe messaging following a suicide</li></ul>

The example programs, policies, and practices have been implemented within particular contexts. The social and cultural context of communities is critically important to take into account when selecting strategies and approaches. Practitioners in the field may be in the best position to assess the needs and strengths of their communities and work with community members to make decisions about the combination of approaches included here that are best suited to their context.

Suicide ideation, attempts, morbidity and mortality vary by gender, race/ethnicity, age, occupation, and other important population characteristics. Barriers to disclosure, help seeking, timely access to quality care, and ongoing support are profoundly complex and may also vary by population and community characteristics. Ideally, the availability of multiple approaches tailored to the economic, cultural, and environmental context of individuals and communities are desirable as they may increase the likelihood of removing barriers to supportive and effective care and provide opportunities to develop individual and community resilience. These culturally appropriate approaches can then be included in comprehensive strategies to maximize the public health impact on reducing suicide-related morbidity and mortality among individuals and within communities.

This package includes strategies where public health agencies are well positioned to bring leadership and resources to implementation efforts. It also includes strategies where public health can serve as an important collaborator (e.g., strategies addressing community and societal level risks), but where leadership and commitment from other sectors such as business/labor or health care is critical to implement a particular policy or program (e.g., workplace policies; screening combined with care management). The role of various sectors in the implementation of a strategy or approach in preventing suicide is described further in the section on *Sector Involvement*.

In the sections that follow, the strategies and approaches with the best available evidence for preventing suicide are described.

## Strengthen Economic Supports

### Rationale

Studies from the U.S. indicate that suicide rates increase during economic recessions marked by high unemployment rates, job losses, and economic instability and decrease during economic expansions and periods marked by low unemployment rates, particularly for working-age individuals 25 to 64 years old (Luo et al., 2011; Fowler et al., 2015). Economic and financial strain, such as job loss, long periods of unemployment, reduced income, difficulty covering medical, food, and housing expenses, and even the anticipation of such financial stress, increase an individual's risk for suicide and how buffering these risks can potentially protect against suicide (Stack & Wasserman, 2007). Public health research suggests that some of the biggest impacts on health come from efforts directed at improving the socioeconomic conditions of individuals and families (Frieden, 2010). Strengthening economic support systems can help people stay in their homes or obtain affordable housing, pay for necessities such as food and medical care, and get job training, among other things. In providing this support, stress and anxiety and the potential for a crisis situation may be reduced, thereby preventing suicide.

### Approaches

Economic supports for individuals and families can be strengthened by targeting household financial security and ensuring stability in housing during periods of economic stress

- **Strengthening household financial security** can reduce the risk of suicide by providing individuals with the financial means to cover basic expenses and lessen the stress and hardship associated with a job loss or other unanticipated financial problems. The provision of unemployment benefits, livable wages, Temporary Assistance to Needy Families (TANF), medical benefits, and retirement and disability insurance to help cover the cost of necessities or to offset costs in the event of disability are examples of ways to strengthen household financial security.
- **Housing stabilization policies** aim to keep people in their homes and provide housing options for those in need during times of financial insecurity. This may occur through programs that provide affordable housing such as through government subsidies or through other options available to potential homebuyers such as loan modification programs, move-out planning, or financial counseling services that help minimize the risk or impact of foreclosures and eviction.

### Potential Outcomes

- Reduced suicide rates
- Lower foreclosure rates
- Lower eviction rates

- Reduced emotional distress

## Evidence

There is evidence suggesting that strengthening household financial security and stabilizing housing can reduce suicide risk.

- **Strengthen household financial security.** An examination of variations in U.S. *unemployment benefit programs* across states demonstrated that the impact of unemployment on suicide was offset in those states that provided greater than average unemployment benefits (Cylus, Glymour, & Avendano, 2014). Another U.S. study examining the link between unemployment and suicide risk using monthly suicide data, length of unemployment, and job losses found that the duration of unemployment, as opposed to just the loss of job, predicted suicide risk (Classen & Dunn, 2012). Together, these results suggest that not only should state unemployment benefit programs be generous in their financial allocations, but also in their duration. Other measures to strengthen household financial security (e.g., transfer payments related to retirement and disability insurance, unemployment insurance compensation, medical benefits, and other forms of family assistance) have also shown an impact on suicide. A study by Flavin and Radcliff (2009) examined the impact of states' per capita spending on transfer payments, medical benefits, and family assistance and total state spending on suicide rates between 1990-2000, controlling for a number of suicide risk factors (e.g., residential mobility, divorce rate, unemployment rate) at the state level. As per capita spending on total transfer payments, medical benefits, and family assistance increased there was an associated decrease in state suicide rates. Moreover, it wasn't spending in general that was associated with the reduction but spending on these types of assistance. In terms of lives saved, Flavin & Radcliff calculated the cost of reducing a state's suicide rate by a full point for the years studied. At the national level, an estimated 3,000 fewer suicides would occur per year nationwide if every state increased their per capita spending on these types of assistance by \$45 per year (Flavin & Radcliff, 2009).
- **Housing stabilization policies.** The *National Neighborhood Stabilization Program* was designed to help neighborhoods suffering from high rates of foreclosure and abandonment by slowing the deterioration of the neighborhoods and providing affordable housing options for low, moderate, and middle-income homebuyers. This program also offers financial assistance to eligible individuals for the purchase of a new home. Although this program has not been rigorously evaluated for its impact on suicide outcomes, it addresses foreclosure and eviction, which are risk factors for suicide. A longitudinal analysis of annual data on suicides and foreclosures demonstrated that as the proportion of foreclosed properties increased in U.S. states, so did the state suicide rate, particularly among working-aged adults (Houle & Light, 2014). Another study of data from 16 U.S. states participating in the National Violent Death Reporting System found

that suicides precipitated by home foreclosures and evictions increased more than 100% from 2005 (before the housing crisis began) to 2010 (after it had peaked; Fowler, Gladden, Vagi, Barnes, and Frazier (2015)). Most of these suicides occurred prior to the actual loss of the decedent's home. These findings suggest that integrating suicide prevention resources, messaging, and referrals into financial, foreclosure, and move-out planning and counseling services may help to prevent suicide.

## Strengthen Access to Mental Health Care

### Rationale

While most people with mental health problems do not attempt or die by suicide (Olfson, Gerhard, Huang, Crystal, & Stroup, 2015; Owens, 2002), and risk conferred by mental illnesses differ (Arsenault-Lapierre, Kim, & Turecki, 2004; E. C. Harris & Barraclough, 1997; Tyrer, Reed, & Crawford, 2015), previous research indicates that mental illness is an important risk factor for suicide (E. C. Harris & Barraclough, 1998; World Health Organization, 2014). Studies suggest that up to 90% of people who die by suicide may have had a mental illness at the time of their deaths (Arsenault-Lapierre et al., 2004; Cavanagh, Carson, Sharpe, & Lawrie, 2003; Isometsa, 2001). State-level suicide rates have also been found to be correlated with general mental health measures such as depression (Lang, 2013; Mark, Shern, Bagalman, & Cao, 2007). Findings from the National Comorbidity Survey indicate that relatively few people in the U.S. with mental health disorders receive treatment for those conditions (Kessler et al., 2005). Lack of access to mental health care is one of the contributing factors related to the underuse of mental health services (Cunningham, 2009). Identifying ways to improve access to timely, affordable, and quality mental health care for people in need is a critical component to suicide prevention (World Health Organization, 2014). Apart from the treatment benefits, it can also serve to normalize help-seeking behavior and increase the use of such services.

### Approaches

One approach to strengthening access to mental health care is through the provision of mental health coverage in health insurance policies.

- **Coverage of mental health conditions in health insurance policies.** Federal and state laws include provisions for equal coverage of mental health services in health insurance plans that is on par with coverage for other health concerns (i.e., mental health parity). Benefits and services covered include such things as the number of visits, co-pays, deductibles, inpatient/outpatient services, prescription drugs, and hospitalizations. If a state has a stronger mental health parity law than the federal parity law, then insurance plans regulated by the state must follow the state parity law. Federal parity replaces the state law only in cases where the state law prevents the application of the federal parity law (e.g., includes coverage for some mental health conditions but not others). Equal coverage does not necessarily imply good coverage as health insurance plans vary in the extent to which benefits and services are offered to address various health conditions. Rather it helps to ensure that mental health services are covered on par with other health concerns.

### Potential Outcomes

- Increased utilization of mental health services

- Decreased symptoms of mental illnesses
- Decreased rates of suicide attempts
- Decreased rates of suicide

## Evidence

There is evidence suggesting that coverage of mental health conditions in health insurance policies can reduce risk factors associated with suicide and may directly impact suicide rates.

- **Coverage of mental health conditions in health insurance policies.** The National Survey of Drug Use and Health is a nationally representative survey of the U.S. population that provides data on substance use, mental health conditions, and services utilization. Using data from this survey, K. M. Harris, Carpenter, and Bao (2006) found that 12 months after states enacted *mental health parity laws*, self-reported use of mental healthcare services significantly increased. Moreover, subsequent research by Lang (2013) examined state mental health laws and suicide rates between 1990 and 2004 and found that mental health parity laws, specifically, were associated with an approximate 5% reduction in suicide rates. This reduction, in the 29 states with parity laws, equated to the prevention of 592 suicides per year and a cost savings of \$1.3-3.1 million per suicide prevented (Lang, 2013).

## Create Protective Environments

### Rationale

**Comment [A]:** Not sure if the additions I made to the rationale are too duplicative of info below. If so, go ahead and delete.

Prevention efforts that focus not only on individual behavior change (e.g., help-seeking, treatment interventions) but on changes to the environment can increase the likelihood of positive behavioral and health outcomes (Haddon, 1980). Creating environments that address risk and protective factors where individuals live, work, and play, can help prevent suicide (Dahlberg & Krug, 2002; U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012). For example, rates of suicide and suicide attempts are elevated in certain occupational groups (Han et al., 2016; McIntosh et al., 2016), therefore, changes to the organizational culture in these occupations, by way of implementation of supportive policies or even physical modifications to the workplace environment, can demonstrate that good health and mental health are valued and that stigma and other risk factors for suicide, are not (K. L. Knox et al., 2010; National Action Alliance for Suicide Prevention Workplace Task Force, 2015). Similarly, changing the availability of and access to common suicide risk factors in the environment such as bridges, alcohol, medications, or firearms, can reduce suicide rates, particularly in times of crisis (Beautrais, Gibb, Fergusson, Horwood, & Larkin, 2009; Crosby, Espitia-Hardeman, Ortega, & Lozano, 2013; Kaplan et al., 2013; Miller, Warren, Hemenway, & Azrael, 2015; C. W. Runyan et al., 2016).

### Approaches

The current evidence suggests three promising approaches for creating environments that protect against suicide.

- **Reducing access to lethal means among persons at-risk of suicide.** Means of suicide such as firearms, hanging/suffocation, or jumping from heights provide little opportunity for rescue and, as such, have high case fatality rates (e.g., about 85% of people who use a firearm in a suicide attempt will die from the injury). Research also indicates that 1) the interval between thinking about and attempting suicide can be as short as 5 or 10 minutes (Deisenhammer et al., 2009; Simon et al., 2001) and 2) that people tend *not* to substitute a different method when a highly lethal method is unavailable or difficult to access (Hawton, 2007; Yip et al., 2012). Therefore, increasing the time interval between the thought and the suicide attempt, for example, by making it more difficult to access lethal means, can be lifesaving. The following are examples of approaches reducing access to lethal means for persons at-risk of suicide:
  - *Intervening at Suicide Hotspots.* Suicide hotspots, or places where suicides may take place relatively easily, include tall structures (e.g., bridges and cliffs), railway tracks, and isolated locations such as parks. Efforts to prevent suicide at these locations include

erecting barriers to prevent jumping and installing signs and telephones to encourage individuals who are considering suicide, to seek help (Cox et al., 2013).

- *Safe Storage Practices.* Safe storage of medications, firearms, and other household products can reduce the risk for suicide by separating individuals who may be vulnerable and/or impulsive from easy access to lethal means. Such practices may include education and counseling around storing firearms--locked in a secure place (e.g., in a gun safe or lock box), unloaded and separate from the ammunition--and keeping medicines in a locked cabinet or other secure location away from people who may be at risk or who have made prior attempts (Rowhani-Rahbar, Simonetti, & Rivara, 2016; C. W. Runyan et al., 2016).
- **Organizational policies and culture** that promote protective environments may be implemented in places of employment. Such policies and cultural values may promote prosocial behavior (e.g., asking for help), skill building, changing social norms, referral and access to helping services (e.g. mental health, substance abuse treatment, financial counseling), and encourage leadership support from the top down. Such policies and cultural shifts can positively impact organizational climate and morale and help prevent suicide and its related risk factors (e.g. depression, social isolation) (National Action Alliance for Suicide Prevention Workplace Task Force, 2015).
- **Community-based policies to reduce excessive alcohol use.** Research studies in the United States have found that greater alcohol availability is positively associated with alcohol-involved suicides (Escobedo & Ortiz, 2002; Giesbrecht et al., 2015). Policies to reduce excessive alcohol use broadly include zoning to limit alcohol outlet locations and density, taxes on alcohol, and bans on the sale of alcohol for individuals under the legal drinking age. These policies are important because acute alcohol use has been found to be associated with more than one-third of suicides and approximately 40% of suicide attempts (Cherpitel, Borges, & Wilcox, 2004).

### Potential Outcomes

- Increase in safe storage of means
- Reduction in suicide attempts
- Reduction in suicide deaths
- Increase in help-seeking
- Reduction in alcohol-related suicide deaths

### Evidence

The evidence for the effectiveness of means restriction and other ways to establish protective environments is some of the strongest in the field (Zalsman et al., 2016), as described below.

- **Reducing access to lethal means among persons at-risk of suicide.** A meta-analysis examining the impact of *suicide hotspot interventions* implemented in combination or in isolation, both in the U.S. and abroad, found associated reduced rates of suicide (Cox et al., 2013; Pirkis et al., 2015). For example, after erecting a barrier on the Jacques-Cartier bridge in Canada, the suicide rate from jumping from the bridge decreased from about 10 suicide deaths per year to about 3 deaths per year (Perron, Burrows, Fournier, Perron, & Ouellet, 2013). Moreover, the reduction in suicides by jumping was sustained even when all bridges and nearby jumping sites were considered, suggesting little to no displacement of suicides to other jumping sites (Perron et al., 2013). Further evidence for the effectiveness of bridge barriers was demonstrated by a study examining the impact of the *removal* of safety barriers from the Grafton Bridge in Auckland, New Zealand. After removal of the barrier, sadly, both the number and rate of suicide increased fivefold (Beautrais, 2001; Beautrais et al., 2009).

Another form of means reduction involves implementation of *safe storage practices*. In a case-control study of firearm-related events identified from 37 counties in Washington, Oregon, and Missouri, and from 5 trauma centers, Grossman et al. (2005) found that storing firearms unloaded, separate from ammunition, in a locked place and/or secured with a safety device was protective of suicide attempts among adolescents. Further, a recent systematic review of clinic and community-based education and counseling interventions suggested that the provision of safety devices significantly increased safe firearm storage practices compared to counseling alone or compared to the provision of economic incentives to acquire safety devices on one's own (Rowhani-Rahbar et al., 2016).

Another program, *The Emergency Department Counseling on Access to Lethal Means (ED CALM)*, trained psychiatric emergency clinicians in a large children's hospital to provide lethal means counseling and safe storage boxes to parents of patients under age 18 receiving care for suicidal behavior. In a pre-post quality improvement project, Runyan et. al (2016) found that at post-test 76% (of the 55% of parents followed up, n=114) reported that all medications in the home were locked up as compared to fewer than 10% at the time of the initial emergency department visit. Among parents who indicated the presence of guns in the home at pre-test (i.e. 67%), all (100%) reported guns were currently locked up at post-test (C. W. Runyan et al., 2016).

- **Organizational policies and culture.** *Together for Life* is a workplace program of the Montreal Police Force implemented to address suicide among officers. Policy and program components were designed to foster an organizational culture that promoted mutual support and solidarity among all members of the Force. The program included training of supervisors, managers and all units to improve competencies in identifying suicidal risk and to improve use and awareness of existing resources. The program also included an education campaign to improve awareness and help-seeking (Mishara & Martin, 2012). Police suicides were tracked over 12 years and

compared to rates in the control city of Quebec. The suicide rate in the intervention group decreased significantly by 78.9% to a rate of 6.42 suicides per 100,000 population per year compared to an 11% increase in the control city (rate: 29.0 per 100,000) (Mishara & Martin, 2012).

Another example of this approach is the *United States Air Force Suicide Prevention Program (AFSPP)*. AFSPP included 11 policy and education initiatives and was designed to change the culture of the Air Force surrounding suicide. The program uses leaders as role models and agents of change, establishes expectations for behavior related to awareness of suicide risk, develops population skills and knowledge (i.e., education and training), and investigates every suicide (i.e., outcomes measurement). The program represents a fundamental shift from viewing suicide and mental illness solely as medical problem and instead sees them as larger service-wide problems impacting the whole community (K. L. Knox, Litts, Talcott, Feig, & Caine, 2003). Using a time-series design to examine the impact of the AFSPP program on various violence-related outcomes, researchers found that the program was associated with a 33% relative risk reduction in suicide (K. L. Knox et al., 2003). The program was also associated with relative risk reductions in related outcomes including moderate and severe family violence (30% and 54%, respectively), homicide (51%), and accidental death (18%) (K. L. Knox et al., 2003). A longitudinal assessment of the program over the period 1981 to 2008 (16 years before the 1997 launch of the program and 11 years post-launch) found significantly lower rates of suicide after the program was launched than before (K. L. Knox et al., 2010). These effects were sustained over time, except in 2004, which the authors found was associated with less rigorous implementation in that year than in the other years (K. L. Knox et al., 2010).

- **Community-based policies to reduce excessive alcohol use.** While multiple policies to limit alcohol use exist, several studies on alcohol outlet *density*, specifically, suggest that measures to reduce alcohol outlet density can potentially reduce alcohol-involved suicides. Additionally, a longitudinal analysis of alcohol outlet density, suicide mortality, and hospitalizations for suicide attempts over 6 years in 581 California zip codes indicated that the density of bars, specifically, is related to suicide and suicide attempts, particularly in rural areas (Johnson, Gruenewald, & Remer, 2009).

## Promote Connectedness to Protect Against Suicide

### Rationale

Sociologist, Emile Durkheim theorized in 1897 that weak social bonds, i.e. lack of connectedness, are among the chief causes for suicidality (Durkheim, 1897/1951). *Connectedness* is the degree to which an individual or group of individuals are socially close, interrelated, or share resources with others (Centers for Disease Control and Prevention, 2009). Social connections can be formed within and between multiple levels of the social ecology (Dahlberg & Krug, 2002), for instance between individuals (e.g. peers, neighbors, co-workers), families, schools, neighborhoods, workplace, faith communities, cultural groups, and society as a whole. Related to connectedness, *social capital* refers to a sense of trust in one's community and neighborhood, social integration, and also the availability and participation in social organizations (Beyer, Layde, Hamberger, & Laud, 2015; Muennig, Cohen, Palmer, & Zhu, 2013). Many ecological cross-sectional and longitudinal studies have examined the impact of aspects of social capital on depression symptoms, depressive disorder, mental health more generally, and suicide. While the evidence is still being built the pattern is towards an inverse association between social capital measured by social trust, community/ neighborhood engagement, and improved mental health. Connectedness and social capital together can serve to protect against suicidal behaviors by decreasing isolation, encouraging adaptive coping behaviors, increasing belongingness, personal value and worth all of which helps individuals to build resilience in the face of adversity. Connectedness can also provide individuals with better access to formal supports and resources, mobilize communities to meet the needs of its members and provide collective primary prevention activities to the community as a whole (Centers for Disease Control and Prevention, 2009).

### Approaches

Promoting connectedness among individuals and within communities through modeling peer norms and enhancing community engagement can protect against suicide.

- **Peer norm approaches** seek to normalize prosocial behaviors/protective factors for suicide such as help-seeking, reaching out and talking to trusted adults, and peer connectedness. These approaches typically target youth and are delivered in school settings but can also be implemented in community settings.

- **Community engagement activities.** Community engagement is an aspect of social capital. Community engagement approaches may involve residents participating in a range of activities, including religious activities, community clean-up and greening activities, and physical exercise. These activities provide opportunities for residents to become more involved in the community and to connect with other community members, organizations, and resources, resulting in enhanced overall physical health, reduced stress, and decreased depressive symptoms, thereby reducing risk of suicide.

### Potential Outcomes

- Reduction in maladaptive coping attitudes and behaviors
- Increase in healthy coping attitudes and behaviors
- Increase in referrals for youth in distressed
- Increase help-seeking behaviors
- Positive perception of adult support

### Evidence

Current evidence suggests that peer norm approaches and community engagement can reduce risk factors associated with suicidal behaviors.

- **Peer norm approaches.** Evaluations show that programs such as *Sources of Strength* can improve school norms and beliefs about suicide that are created and disseminated by student peers. In a randomized controlled trial of *Sources of Strength* conducted with 18 high-schools (6 metropolitan, 12 rural), Wyman et al. (2010) found that the program improved peer leaders' adaptive norms regarding suicide, their connectedness to adults, and school engagement. Peer leaders were also more likely than controls to refer a suicidal friend to an adult. Among students, the intervention increased perceptions of adult support for suicidal youths and the acceptability of seeking help. Perception of adult support increased most in students with a history of suicidal ideation. Finally, trained peer leaders also reported a greater decrease in maladaptive coping attitudes compared with untrained leaders (Wyman et al., 2010).
- **Community engagement activities.** A vacant lot greening initiative was undertaken in Philadelphia between 1999 and 2008. Local residents and community members worked together to green 4,436 lots (or 7.8 million square feet) in 4 areas of the city. Researchers found significant associated reductions in community residents' self-reported stress levels and engagement in more physical exercise than residents in control vacant lot areas. Other benefits included reductions in firearm assaults and vandalism (Branas et al., 2011).

## Teach Coping and Problem-Solving Skills

### Rationale

Building life skills prepares individuals to successfully tackle every day challenges and adapt to stress and adversity. Life skills encompasses many concepts, but most often include coping and problem-solving skills, conflict resolution, and critical thinking. Life skills are important in shielding individuals from suicidal behaviors (World Health Organization, 2014). Suicide prevention programs that focus on life and social skills training are drawn from social cognitive theories (Bandura, 1986), surmising that individuals who engage in suicidal behavior is attributed to either direct learning, modeling, and environmental and individual (e.g. hopelessness) characteristics. The literature linking life skills and suicide is robust--- The inability to employ adequate coping strategies to cope with immediate stressors or identify and find solutions for problems have been characterized among suicide attempters (Pollock & Williams, 2004). Treatments that include bolstering problem skills (Goldsmith, Pellmar, Kleinman, & Bunney, 2002) and include problem-solving techniques (Ghahramanlou-Holloway, Bhar, Brown, Olsen, & Beck, 2012; Townsend et al., 2001) appear to reduce suicidal ideation and attempts more effectively. Prevention programs focused on teaching these skills target youth, parents and families and have been used with both universal and at-risk populations. While many do not target suicidal behaviors directly, these programs strive to train youth and parents important life skills to offset the underlying vulnerabilities that contribute to engaging in high risk behaviors early in life.

### Approaches

Current evidence provides support for the following two approaches:

- **Social emotional learning programs** focus on developing and strengthening communication and problem-solving skills, emotion regulation, conflict resolution, help seeking and coping skills. These approaches address a range of risk and protective factors for suicidal behavior. They provide children and youth with skills to resolve problems in relationships, school, and with peers, and help youth to address other negative influences (e.g., substance use) associated with suicide. These approaches are typically delivered to all students in a particular grade or school, although some programs also focus on groups of students considered to be at high-risk for suicide. Opportunities to practice and reinforce skills are an important part of programs that work (Herman, Borden, Reinke, & Webster-Stratton, 2011).
- **Parenting skill and family relationship programs** are designed to strengthen parenting skills, enhance positive parent-child interactions, and improve children's behavioral and emotional skills and abilities. Several parenting and family relationship programs have been shown in rigorous evaluations to improve resilience and reduce risk factors for various behaviors, including

ones closely related to suicide, such as depression, internalizing behaviors, and substance abuse (M. S. Knox, Burkhart, & Hunter, 2010).

### Potential Outcomes

- Reduction in suicide attempts and suicide ideation
- Enhanced knowledge of risk and protective factors associated with suicide
- Reduction in suicide risk behaviors (i.e., depression, anxiety, conduct problems, substance abuse)
- Improve and normalize help-seeking behavior
- Enhance social competence and emotional regulation skills
- Enhance problem-solving and conflict management skills

### Evidence

There are several programs with evidence that support teaching social, emotional and parenting skills to reduce suicidal behaviors and associated risk factors.

- **Social emotional learning programs.** The *Youth Aware of Mental Health Program (YAM)* is a program developed for teenagers that uses interactive dialogue and role-playing to teach adolescents about the risk and protective factors associated with suicide (including knowledge about depression and anxiety) and enhances their problem-solving skills for dealing with adverse life events, stress, school and other problems. The program includes 3 hours of role-play sessions and interactive workshops combined with a booklet that students can keep, educational posters displayed in classroom, and interactive lectures about mental health at the beginning and end of the program (Wasserman et al., 2014). In a cluster-randomized controlled trial of YAM conducted across 10 European Union countries and 168 schools, students participating in the YAM program were significantly less likely to have an incident suicide attempt (OR 0.45, 95%CI 0.24–0.85;  $p=0.014$ ) and severe suicidal ideation (0.50, 0.27-0.92;  $p=0.025$ ) at the 12-month follow-up compared to the control group. Additionally, related to severe suicide ideation, in the YAM group absolute risk fell by 0.50% and RR fell by 49.6% (Wasserman et al., 2014).

*Signs of Suicide (SOS)* is another school-based prevention program for students aged 13-17. The program includes guided classroom discussions about suicide and depression. As part of the program, students are screened for depression and suicide risk and referred for professional help as indicated. The program is designed to increase knowledge about suicide and risk factors associated with suicidal behavior as well as improve and normalize help-seeking behavior (Schilling, Aseltine, & James, 2016). In a randomized controlled trial, SOS was shown to reduce self-reported suicide attempts at 3-months post intervention among

participating students compared to control students. The SOS program also increased students' knowledge of how to get help for themselves or friends for depression and/or suicidal thoughts, and favorable attitudes toward help-seeking. SOS participants with a lifetime history of suicide attempt were also less likely to report planning a suicide in the 3 months following the program compared to lower-risk participants (Schilling et al., 2016).

Finally, the *Good Behavior Game (GBG)* is a classroom-based program for elementary school children aged 6-10; it represents an example of upstream suicide prevention programming. The program uses a team-based behavior management strategy that promotes good behavior by setting clear expectations for good behavior and consequences for maladaptive behavior. The goal of the GBG is to create an integrated classroom social system that is supportive of all children being able to learn with little aggressive or disruptive behavior (Wilcox et al., 2008). In an outcome evaluation of the GBG, first graders assigned to GBG reported half the adjusted odds of suicidal ideation and suicide attempts. The beneficial effect of the program was consistent for suicidal ideation regardless of whether baseline covariates were included. The GBG effect on attempts was less robust in some adjusted models including caregiver mental health. In the second cohort of GBG students, neither suicidal ideation nor suicide attempts were significantly different between GBG and the control interventions (Wilcox et al., 2008). This finding likely arose due to the lack of implementation fidelity and pointed to the need for GBG to be delivered with precision, consistency, and teacher support. GBG was also found to be associated with reduced risk of later substance abuse, a risk factor for suicide (Kellam et al., 2008).

- **Parenting skill and family relationship programs.** Parenting and family skills training approaches have shown promising impacts in preventing key risk factors associated with suicide. For example, the *Incredible Years (IY)* is a comprehensive group training program for parents, teachers and children designed to reduce conduct and substance abuse problems, two important suicide risk factors, in youth by improving protective factors such as responsive and positive parent-teacher-child interactions and relationships, emotion self-regulation and social competence (all protective factors for suicide) (Herman et al., 2011). The program includes 9- 20 sessions offered in community-based settings (e.g., religious, recreation centers, mental health treatment centers, and hospitals). Several studies have demonstrated the effect of the IY program on reducing internalizing symptoms, such as anxiety and depression, and child conduct problems (C. H. Webster-Stratton, Reid, & Beauchaine, 2011; Webster-Stratton, Jamila Reid, & Stoolmiller, 2008). The program is also associated with improved problem-solving and conflict management; these skills were maintained at 1-year follow-up (Reid, Webster-Stratton, & Hammond, 2003; C. Webster-Stratton & Hammond,

1997; C. Webster-Stratton, Reid, & Hammond, 2001). The program demonstrated greater benefits as the dosage of the intervention increased (Herman et al., 2011).

Additionally, *Strengthening Families 10-14* is a program that involves sessions between parents, youth, and family with the goal of improving parents' skills for disciplining, managing emotions and conflict, and communicating with their children; promoting youths' interpersonal and problem-solving skills; and creating family activities to build cohesion and positive parent-child interactions. The premise of the program is that developing these skills for both parents and children will reduce internalizing behavior and adolescent substance abuse, two important risk factors for suicide (Spoth, Gyll, & Day, 2002). *Strengthening Families* has been shown to decrease externalizing behaviors, alcohol use, and drug use among youth participants and reductions in depression, alcohol use, and drug use among participating families (Spoth et al., 2002).

## Identify and Support People At-Risk

### Rationale

In order to decrease suicide, attention to people at increased or high risk is necessary as these individuals tend to experience suicidal behavior at higher than average rates. These vulnerable or disadvantaged populations include, but are not limited to, individuals with lower socio-economic status or who are living with a mental health problem; people who have attempted suicide previously, individuals who are institutionalized, have been victims of violence, or are homeless; and members of certain ethnic minority groups. Supporting these vulnerable groups requires proactive case finding along with access to, and retention in, mental health services. Finding effective ways of identifying at-risk or vulnerable groups, customizing services to make them accessible and maintaining care remain key challenges. For example, simply improving services does not guarantee that those services will be used by those most in need of them, nor will it necessarily increase the number of people who follow treatments that are recommended. People who are disadvantaged face social and economic issues that may adversely affect their ability to respond to the treatments or advice that are offered.

### Approaches

The following three approaches focus on identifying and supporting people at increased risk.

- **Gatekeeper training** is designed to train teachers, coaches, providers and others in the community to identify people who may be at risk of suicide and to respond effectively, including facilitating treatment seeking and support services. Gatekeeper training is typically implemented in schools to identify at-risk youth and within health care settings to identify adults (and youth).
- **Screening combined with care management and overall continuity of care** has been used in primary care and behavioral health care settings to assure that people who may be at high-risk of suicide are identified and receive ongoing treatment as needed, particularly after inpatient discharge and other transitions within the healthcare system so they don't 'slip through the cracks'. These approaches typically employ screening for depression and/or suicide combined with collaborative treatment planning between patients and their providers and patient follow-up.
- **Crisis intervention.** These approaches provide support and referral services, typically by connecting a person in crisis (or a friend or family member of someone at-risk) to trained volunteers and/or professional staff via telephone hotline, online chat, or text messaging. Crisis intervention approaches are intended to impact key risk factors for suicide, including feelings of depression, hopelessness, and subsequent mental health care utilization. Like means reduction,

crisis interventions can put space or time between an individual who may be considering suicide and harmful behavior.

### Potential Outcomes

- Reduction in suicide attempts
- Reduction in suicide deaths
- Increased identification of individuals at-risk for suicidal behavior
- Increased at-risk individuals in treatment
- Increased community members trained to identify at-risk individuals
- Increased referrals for health care

### Evidence

There is evidence that community gatekeeper programs are successful in reducing suicides and suicide attempts but the efforts must be maintained (Substance Abuse and Mental Health Services Administration, 2014). However, there is limited evidence for effectiveness screening programs, but at the same time, standard principles for public health screening make them promising (Pena & Caine, 2006). The number of studies evaluating crisis intervention services is limited, but a few studies do indicate that those who use the hotline services have decreased suicidal thoughts and behavior.

- **Gatekeeper training.** One example of gatekeeper training is the *Mental Health First Aid (MHFA)* program. This program is designed for the lay public and consists of three weekly sessions of three hours each. Participants learn the symptoms of people in mental health crises and/or in the early stages of mental health problems (i.e., those experiencing suicidal thoughts and behavior, acute stress reaction, panic attacks and acute psychotic behavior, and depression, anxiety, and psychotic disorders), possible risk factors, and where and how to get evidence-based effective help (Kitchener & Jorm, 2004). In a randomized controlled trial of 300 participants of *MHFA*, the intervention group reported greater confidence in providing help to others, greater likelihood of advising people to seek professional help, improved concordance with health professionals about treatments, and decreased stigmatizing attitudes. Additionally, the intervention resulted in improved mental health of the participants themselves. All results were statistically significant at  $p < .05$ . (Kitchener & Jorm, 2004). Additional research rigorously evaluating *MHFA* for its impact on the first aid recipients themselves and suicidal behavior is needed (Kitchener & Jorm, 2006).

Gatekeeper training has also been a core part of all *Garret Lee Smith (GLS) Suicide Prevention Program* which is in place in 49 states and 48 tribes. A multi-site evaluation assessed the

connection between community gatekeeper training and a reduction of suicide attempts and deaths by comparing the change in suicide mortality rates and nonfatal suicidal behavior among the population aged 10-24 in counties implementing *GLS* trainings, with the trajectory observed in similar counties that did not implement these trainings. Counties implementing *GLS* trainings had significantly lower youth suicide rates the year following the training implementation (-1.07,  $p=.03$ ) (Walrath, Garraza, Reid, Goldston, & McKeon, 2015) This finding represents a decrease of 1 suicide death per 100,000 10 to 24 year olds or the avoidance of approximately 237 deaths in this age group between 2007 and 2010. Counties implementing *GLS* program activities also had significantly lower suicide attempt rates among youths 16 to 23 years of age in the year following implementation of the *GLS* program than did similar counties that did not implement *GLS* program activities (4.9 fewer attempts per 1000 youths [95% CI, 1.8-8.0 fewer attempts per 1000 youths];  $p = .003$ ; (Godoy Garraza, Walrath, Goldston, Reid, & McKeon, 2015)). More than 79 000 suicide attempts may have been averted during the period studied following implementation of the *GLS* program.

- **Screening combined with care management and overall continuity of care.** The *Henry Ford Perfect Depression Care* program was the pre-cursor to *Zero Suicide*, and its overall goal was to eliminate suicide. More broadly, though, the aim was to completely redesign depression care delivery to achieve breakthrough improvement in quality and safety by focusing on six aims: effectiveness, safety, patient centeredness, timeliness, efficiency, and equity among patients. The program developed concrete measures to assess progress on each of these aims and began with screening and assessment of each patient for suicide risk with coordinated continuous follow-up care system wide (C. E. Coffey, 2006). An examination of the impact of the *Henry Ford Perfect Depression Care (Pre-cursor to Zero Suicide)* program found that there was a dramatic and statistically significant decrease in the rate of suicide between the baseline years prior to the intervention (1999 and 2000) to the intervention years (2002-2009). During this time period, the suicide rate fell 82% (C. E. Coffey, 2006; C. E. Coffey, Coffey, & Ahmedani, 2013). Further, suicide rates also declined among HMO members who participated in targeted suicide prevention efforts and received mental health specialty services. However, for those HMO members who accessed only general medical services as opposed to specialty mental health services, the suicide rate increased (M. Coffey, Coffey, & Ahmedani, 2015).
- **Crisis intervention.** Suicide prevention hotlines are one way to provide crisis intervention. In an evaluation of the effectiveness of the *National Suicide Prevention Lifeline (NSPL)* to prevent suicide, 1,085 suicidal individuals who called the hotline completed a standard risk assessment for suicide, and 380 of those completed a follow-up assessment between 1 and 52 days after the initial assessment. Researchers found that over half of the initial sample were seriously considering suicide when they called, and they had a plan for their suicide. Researchers also

found that participants experienced significant decreases in suicidality over the course of the telephone session, and that levels of hopelessness and psychological pain continued to decrease after their initial call (Gould, Kalafat, Harrismunfakh, & Kleinman, 2007).

In another study, this time employing a randomized controlled trial, Gould, Cross, Pisani, Munfakh, and Kleinman (2013) assessed the impact of the *Applied Suicide Intervention Skills Training (ASIST)*, a widely implemented training program that helps hotline counselors, emergency workers, and other gatekeepers to identify and connect with suicidal individuals, understand their reasoning for living and dying, and assist with safely connecting those in need to available resources. The training was evaluated across the NSPL network of hotlines over the period 2008-2009. Using data from 1,410 suicidal individuals who called 17 Lifeline centers, researchers found that compared to callers who spoke to counselors that received the usual care training, individuals who spoke with counselors trained in *ASIST* were significantly more likely to feel less depressed, less suicidal, less overwhelmed, and more hopeful by the end of their call to the hotline. Counselors trained in *ASIST* were also more skilled at keeping callers on the phone longer and establishing a connection with them. However, training in *ASIST* did not result in more comprehensive suicide risk assessments than usual care training (Gould et al., 2013).

## Intervene to Lessen Harms and Prevent Future Risk

### Rationale

Individuals who have experienced mental health challenges, suicidal ideation, and/or who have made suicide attempts and/or have engaged in non-suicidal self-injury are at increased risk of suicide (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012). Risk of suicide can also increase among those who have lost a friend, family member, co-worker, or other acquaintance to suicide (Pitman, Osborn, King, & Erlangsen, 2014). Exposure to sensationalized or uninformed reporting regarding on suicide may heighten the risk of suicide among vulnerable individuals and can inadvertently contribute to suicide contagion (Etzersdorfer & Sonneck, 1998; Niederkrotenthaler & Sonneck, 2007).

### Approaches

A broad array of approaches to lesson harms and reduce future risk of suicide among those at increased risk include the provision of mental health care and improved continuity of care, improving linkage to care through active post-discharge planning and follow-up that decreases barriers to ongoing therapeutic support, increasing connectedness to supportive others, addressing bereavement, and framing communications to emphasize resilience, decrease negative affect, and to prevent contagion.

- **Treatment for people at-risk of suicide** typically includes various forms of psychotherapy delivered by licensed providers to help individuals with mental health problems and other risk factors for suicide with problem-solving, impulsivity and emotion regulation.
- **Treatment to prevent re-attempts.** These approaches typically include follow-up contact and use diverse modalities (e.g., home visits, mail, telephone, e-mail) to engage recent suicide attempt survivors in continued treatment to prevent re-attempts. Treatment may focus on improved coping skills, mindfulness, and other emotional regulation skills, and may include case management home visits to increase adherence to treatment and continuity of care; and one-on-one interpersonal therapy and/or group therapy. Approaches that engage and connect attempters to peers and providers are especially important because many attempters do not present to aftercare; 12%-25% reattempt within a year, and 3%-9% of attempt survivors die by suicide within 1 to 5 years of their initial attempt (Inagaki et al., 2015)
- **Postvention** approaches are implemented *after* a suicide has taken place and may include debriefing sessions, counseling, and/or bereavement support groups for surviving friends and family members/loved ones. These programs have not typically been evaluated for their impact on suicide or suicidal behavior but may reduce survivors' guilt, feelings of depression, and complicated grief (Szumilas & Kutcher, 2011).

- **Safe messaging following a suicide.** The manner in which information on a recent suicide is communicated to the public (e.g. school assemblies, mass media, social media) can heighten the risk of suicide among vulnerable individuals and can inadvertently contribute to suicide contagion. Therefore, responsible and safe reporting may help prevent suicide and/or suicide contagion.

#### Potential Outcomes

- Reduction in mental health-related sequelae
- Increase connectedness
- Improved coping skills
- Improved messaging following suicide
- Reduction in re-attempts

#### Evidence

The evidence addressing strategies to lesson harm and prevent future risk of suicide includes the evaluation of effects of specific approaches on risk and protective factors as well as suicide-related mortality. However, because the evaluation of suicide-related mortality requires large sample sizes and extended follow-up, much of the evidence in this area primarily focuses on risk and protective factors.

- **Treatment for people at-risk of suicide.** There are a number of treatments with evidence of impact on risk and protective factors for suicide. One example is the *Improving Mood – Promoting Access to Collaborative Treatment (IMPACT)* program. IMPACT aims to prevent suicide among older primary care patients by reducing suicide ideation and depression in primary care settings. It facilitates the development of a therapeutic alliance, a personalized treatment plan that includes patient preferences, as well as proactive follow-up (biweekly during an acute phase and monthly during continuation phase) by a depression care manager (Hunkeler et al., 2006). The program has been shown to significantly improve quality of life, and to reduce functional impairment, depression and suicidal ideation over 24-months of follow-up (Hunkeler et al., 2006; Unutzer et al., 2006) relative to patients who received care as usual.

Another example is *Collaborative Assessment and Management of Suicidality (CAMS)*, which is a therapeutic approach for suicide-specific assessment and treatment of patient's suicide risk. This flexible approach can be used across treatment settings and clinician theoretical orientations and involves the clinician and patient working together in an interactive assessment process to develop patient-specific treatment plans. CAMS sessions are collaborative and involve constant

**Comment [A]:** The write-up of the evidence for this strategy needs to follow the format used in the other sections of the TP. I modified the write-up for the first approach to illustrate the format. You will need to do something similar for the second approach.

patient about what is and is not working with the ultimate goal of enhancing the therapeutic alliance and increasing treatment motivation in the suicidal patient. CAMS been tested and supported in 6 correlational studies (Jobes, 2012), in a variety of inpatient and outpatient settings and in one RCT with several additional RCTs under way. CAMS has been associated with significant improvements in suicidal ideation, overall symptom distress, and feelings of hopelessness at 12 month follow-up among a community-based sample of suicidal outpatients. (Comtois et al., 2011).

Other examples include *Dialectical Behavioral Therapy (DBT)* and *Attachment-Based Family Therapy (ABFT)*. DBT is a multicomponent therapy for individuals at high risk for suicide and who may struggle with impulsivity and emotional regulation. The components of DBT include individual therapy, group skills training, between-session telephone coaching and a therapist consultation team. In a randomized controlled trial of women with recent suicidal or self-injurious behavior, those receiving DBT were half as likely to make a suicide attempt at two-year follow-up than women receiving community treatment (23% vs 46%), required less hospitalization for suicide ideation, and had lower medical risk across all suicide attempts and self-injurious acts combined (Linehan et al., 2006).

ABFT is a program for adolescents aged 12-18 and is designed to treat clinically diagnosed major depressive disorder, eliminate suicidal ideation, and reduce dispositional anxiety (Diamond et al., 2010). A randomized controlled trial of ABFT found that suicidal adolescents assigned to ABFT experienced significantly greater improvement in suicidal ideation over 24 weeks of follow-up than did adolescents assigned to enhanced usual care (-4.37 vs. -2.34;  $p = .001$ ;  $d=0.97$ ). Additionally, a higher percentage of ABFT participants reported no suicidal ideation in the week prior to assessment at 12 weeks than did adolescents receiving enhanced usual care (69.2% vs. 34.6%;  $p = .01$ ; OR= 4.25) and at 24 weeks (82.1% vs. 46.2%;  $p = .006$ ; OR=5.37) (Diamond et al., 2010).

- **Treatment to prevent re-attempts.** Several strategies that aim to prevent re-attempts among those at risk for suicide have demonstrated impact on reducing suicidal behavior. For example, *Emergency Department Brief Intervention with Follow-up Visits* is a program that involves a one-hour discharge information session that addresses suicidal behavior, distress, risk and protective factors, alternatives to suicidal behavior, and referral options, combined with nine follow-up contacts over 18-months (at 1, 2, 4, 7, 11 weeks and 4, 6, 12, 18 months). Follow-up contacts are either conducted by phone or through home visits according to a specific time line for up to 18-months. A randomized controlled trial that enrolled suicide attempters from eight hospital emergency departments in five culturally different sites found that a brief intervention combined with 9 follow-up visits over 18-months was associated with significantly fewer deaths from

suicide relative to a treatment-as-usual group (0.2% versus 2.2%, respectively;  $\chi^2 = 13.83$ ,  $P < 0.001$ ) (Fleischmann et al., 2008).

Another example of treatment to prevent re-attempts involves active follow-up contact approaches such as postcards, letters, and telephone calls, are intended to increase a patient's sense of connectedness with health care providers and decrease isolation. These approaches include expression of care and support and typically invite patients to reconnect with their provider. Contacts are made periodically (e.g., monthly or every few months in the first 12 months post-discharge with some programs continuing contact for 2 or more years). These approaches have been found in a meta-analysis conducted by Inagaki et al. (2015) to reduce reattempts by approximately 17% for up to 12 months post-discharge, however, the long-term effects of these approaches on reattempts has not yet been demonstrated. Also, because the number of trials and associated sample sizes included in this meta-analysis were small, it was not possible to determine the effect of active contact and follow-up approaches on death by suicide. In a randomized controlled trial of post-crisis suicide prevention long-term follow-up contact approach, Motto and Bostrom (2001) found that patients who refused ongoing care but who were randomized to be contacted by letter four times per year had a lower rate of suicide over two years of follow-up than did patients in the control group who received no further contact. Other studies have also shown post-crisis letters and coping cards to be protective against suicide ideation and attempts (Hassanian-Moghaddam, Sarjami, Kolahi, & Carter, 2011; Wang et al., 2016).

Finally, *Cognitive Behavior Therapy for Suicide Prevention (CBT-SP)* is an example of a therapeutic approach to prevent re-attempts. It uses a risk reduction, relapse prevention approach that includes an analysis of proximal risk factors and stressors (e.g., relationship problems, school or work-related difficulties) leading up to and following the suicidal event; safety plan development; skill building; and psychoeducation. *CBT-SP* also has family skill modules focused on family support and communication patterns as well as improving the family's problem solving skills. A randomized controlled trial found of *CBT-SP* found that 10-session outpatient cognitive therapy designed to prevent repeat suicide attempts resulted in a 50% reduction in the likelihood of a suicide reattempt among adults who had been admitted to an emergency department for a suicide attempt relative to treatment as usual (Brown et al., 2005).

- **Postvention** programs are implemented with the goal of providing support to survivors of suicide to reduce their own risk of suicide. One example of a postvention program, *StandBy Response Service (StandBy)*, provides clients with face-to-face outreach and telephone support through a professional crisis response team. Site coordinators develop customized case management plans, referring clients to other existing community services matched to their needs (Visser, Comans, &

Scuffham, 2014). In a study by Visser et al. (2014), *StandBy* clients were significantly less likely to be at high risk for suicidality than a suicide bereaved comparison group who had not had contact with the *StandBy* program (48% and 64% respectively,  $p = 0.005$ ). Additionally, research suggests that active postvention approaches in which outreach to suicide survivors occurs at the scene of a suicide is associated with intake into treatment sooner, greater attendance at support group meetings, and attendance at more meetings compared to passive postvention (versus passive approaches where survivors self-refer for services) (J. Cerel & Campbell, 2008).

- **Safe messaging following a suicide.** One way to ensure safe messaging following a suicide is to encourage that reporters adhere to *media guidelines for reporting on suicides*. Such guidelines can help assure that stories on suicide are communicated in an effective way that reduces risk to others who may be vulnerable. Reports that are both inclusive of suicide prevention messages, stories of hope and resilience, risk and protective factors, and links to helping resources (e.g., hotline) and that avoid sensationalizing events or reducing suicide to one cause can help reduce the likelihood of suicide contagion. The most compelling evidence supporting the effect of *media guidelines* on reduction in suicides comes from Austria. After a sharp increase in suicides on the Viennese subway, media guidelines were introduced and an interrupted time series design was used to evaluate the national impact of the guidelines on subsequent suicides. Changes in the quality and quantity of media reporting resulted in a reduction of 81 suicides annually (95% confidence interval: -149 to -13;  $t = -2.32$ ,  $df = 54$ ,  $p < 0.024$ ) in the Viennese subway system (Niederkrötenenthaler & Sonneck, 2007)

## Sector Involvement

Public health can play an important and unique role in addressing suicide. Public health agencies, which typically place prevention at the forefront of efforts and work to create broad population-level impact, can bring critical leadership and resources to bear on this problem. For example, these agencies can serve as a convener, bringing together partners and stakeholders to plan, prioritize, and coordinate suicide prevention efforts. Public health agencies are also well positioned to collect and disseminate data, implement preventive measures, evaluate programs, and track progress. Although public health can play a leadership role in preventing suicide, the strategies and approaches outlined in this technical package cannot be accomplished by the public health sector alone.

Other sectors vital to implementing this package include, but are not limited to, education, government (local, state, and federal), social services, health services, business/labor, justice, housing, media, and organizations that comprise the civil society sector such as faith-based organizations, youth-serving organizations, foundations, and other non-governmental organizations. Collectively, these sectors can make a difference in preventing suicide by impacting the various contexts and underlying risks that contribute to suicide.

The strategies and approaches described in this technical package are summarized in Appendix A along with the relevant sectors that are well positioned to lead implementation efforts.

[Linda to insert text specific to the strategies and approaches]

Regardless of strategy, action by many sectors will be necessary for the successful implementation of this package. In this regard, all sectors can play an important and influential role in creating safe and protective environments where individuals who are at high risk of suicide can easily access the mental healthcare and services they need.

## Monitoring and Evaluation

Monitoring and evaluation are necessary components of the public health approach to prevention. It is important to have timely and reliable data to monitor the extent of the problem and to evaluate the impact of prevention efforts. Data are necessary for program implementation; planning, implementation, and assessment all rely on accurate measurement of the problem.

Surveillance data helps researchers and practitioners track changes in the burden of suicide. Surveillance systems exist at the federal, state, and local levels. It is important to assess the availability of surveillance data and data systems across these levels to identify and address gaps in the systems. CDC's National Vital Statistics System and the National Violent Death Reporting System (NVDRS) are examples of surveillance systems that provide data on deaths from suicide. NVDRS, for example, is a state-based surveillance system that combines data from death certificates, law enforcement reports, and coroner or medical examiner reports to provide detailed information on the circumstances of violent deaths, including suicide, which can assist communities in guiding prevention approaches (Blair, Fowler, Jack, & Crosby, 2016). The National Electronic Injury Surveillance System-All Injury Program (NEISS-AIP) provides nationally representative data about all types and causes of nonfatal injuries treated in U.S. hospital emergency departments, and can be used to assess national rates of, and trends in, self-harm injuries by cause (e.g., falls, poisoning, etc.), age, race/ethnicity, sex, disposition (where the injured person goes when released from the Emergency Department).

In addition to information on deaths and nonfatal injuries, there are also surveillance systems that provide national, state, and some local estimates of suicidal behavior. The Youth Risk Behavior Surveillance System (YRBSS) collects information from a nationally representative sample of 9-12 grade students and is a key resource in monitoring health-risk behaviors among youth, including whether youth have seriously considered attempting suicide, attempted suicide, made a plan, or required treatment by a doctor or nurse for a suicide attempt that resulted in an injury, poisoning, or overdose (Brener et al., 2013). The YRBSS data are obtained from a national school-based survey conducted by CDC as well as school-based state, territorial, tribal, and large urban school district survey conducted by education and health agencies. The National Survey on Drug Use and Health (NSDUH) is an annual nationwide survey of individuals aged 12 years and older that provides national and state-level estimates of drug use and mental health-related issues, including suicide ideation and suicide attempts.

It is also important at all levels (local, state, and federal) to address gaps in responses, track progress of prevention efforts and evaluate the impact of those efforts, including the impact of this technical package. Evaluation data, produced through program implementation and monitoring, is essential to provide information on what does and does not work to reduce rates of suicide and its associated risk and protective factors. Theories of change and logic models that identify short, intermediate, and long-term outcomes are an important part of program evaluation.

The evidence-base for suicide prevention has advanced greatly over the last few decades. However, additional research is needed to understand the impact of prevention programs on preventing suicide, as opposed to merely examining the effectiveness of programs to impact risk factors associated with suicide. More research is also needed to examine the effectiveness of upstream and community-level strategies to prevent suicide at the population level. Lastly, it will be important for researchers to test the effectiveness of combinations of the strategies and approaches included in this package. Most existing evaluations focus on approaches implemented in isolation. However, there is potential to understand the synergistic effects within a comprehensive prevention approach. Additional research is needed to understand the extent to which combinations of strategies and approaches result in greater reductions in suicide than individual programs, practices, or policies.

## Conclusion

Suicide is a serious public health problem whose rates have been on the rise for more than a decade and whose costs stretch well into the billions of dollars each year. And while suicide is a rare outcome statistically, its human impact has a ripple effect that is far-reaching. Each of us likely interacts with suicide survivors, those with lived experience, and those with thoughts of suicide, on a daily basis—at home, at work, and in our communities. Suicide and suicide attempts are therefore public health issues of societal concern. Fortunately, like many public health problems, suicide is preventable, and fortunately more is being done to prevent suicide than ever before, as evidenced by the work of the National Action Alliance for Suicide Prevention, the release of the first world report on suicide, more timely surveillance data, and critical mention in the President’s FY17 budget, to name just a few examples. Unfortunately and unlike most other public health problems, suicide still struggles against stigma, shame, and secrecy related to help-seeking, mental illness, being a survivor, or someone with lived experience; misplaced fear of asking someone about their risk of suicide (versus the fear and consequence of not asking), and fear of taking up certain strategies known to be effective but perhaps unpopular; misinformation about suicide preventability, and disproportionate funding given the public health burden. Suicide also struggles against the right degree of awareness where too much information, for example by well-meaning reporters and others, may actually do harm.

In an effort to continue pushing the field and society further towards prevention, this technical package includes strategies and approaches that ideally would be used in a comprehensive fashion, in combination—in a multi-level, multi-sectoral way. This technical package includes strategies and approaches targeting upstream prevention, e.g., social emotional learning for children and youth, as well as strategies focused more downstream, e.g., cognitive behavioral treatment to prevent re-attempts. It includes universal, selective, and indicated strategies, or strategies that focus on the whole population regardless of risk to strategies that focus on those groups at highest risk. Importantly, this technical package extends the bounds of the typical prevention strategies to consider approaches at the outer

levels of the social ecology, e.g., policies to stabilize housing and community engagement initiatives. In short, care and attention has been paid to all aspects of suicide prevention.

While the evidence base continues to be built, the collection of programs, policies, and practices laid out here are available for implementation now. And in keeping with good public health practice, the intent is that monitoring and evaluation will play a key role in that implementation. Moreover, as new evidence becomes available, this technical package can be refined to reflect the current state of the science.

In closing, and in keeping with a message of resilience as spoken by those with lived experience, ‘hope, help, and healing is possible.’

## Appendix A: Summary of Strategies and Approaches to Prevent Suicide

Strategy	Approach/Program, Practice or Policy	Best Available Evidence			Lead Sectors <sup>1</sup>
		Suicide	Suicide Attempts or Ideation	Other Risk/Protective Factors for Suicide	
Strengthen economic supports	Strengthen household financial security				
	Unemployment benefit programs	✓			Government (local, state, Federal)
	Housing stabilization policies				
	The National Neighborhood Stabilization Program			✓	Government (local, state, Federal)
Strengthen access to mental health care	Coverage of mental health conditions in health insurance policies				
	Mental Health Parity Laws	✓		✓	Government (state, Federal)  Health care
Establish protective environments	Reducing access to lethal means among persons at-risk				
	Intervening at hot spots	✓			Government (local, state, Federal)
	Safe storage practices		✓	✓	Public Health
	Organizational policies and culture				
	Together for Life	✓			Business/Labor

		Best Available Evidence			
	<i>US Air Force Suicide Prevention Program</i>	✓		✓	Government (local, state, Federal)
	Community-based policies to reduce excessive alcohol use				
	<i>Alcohol outlet density</i>	✓		✓	Government (local, state, Federal)
Promote connectedness to protect against suicide	Peer norm approaches				
	<i>Sources of Strength</i>			✓	Public Health Social Services
	Community-engagement activities				
	<i>Greening vacant urban spaces</i>			✓	Public Health
Teach coping and problem- solving skills	Social emotional learning				
	<i>Youth Aware of Mental Health Program</i>		✓		Public Health
	<i>Signs of Suicide</i>		✓	✓	Education
	<i>Good Behavior Game</i>		✓	✓	
	Parenting skill and family relationship approaches				
	<i>The Incredible Years</i>			✓	Public Health
				Education	

		Best Available Evidence			
	<i>Strengthening Families 10-14</i>			✓	
Identify and support people at-risk	Gatekeeper training				
	<i>Mental Health First Aid</i>			✓	Public Health Healthcare Social Services
	Screening combined with care management				
	<i>Henry Ford Perfect Depression Care (Pre-cursor to Zero Suicide)</i>	✓		✓	Healthcare
	Crisis Intervention				
	<i>National Suicide Prevention Lifeline</i>		✓	✓	Public Health Social Services
	<i>Applied Suicide Intervention Skills Training</i>		✓	✓	
Treatment for people at risk of suicide					
	<i>Improving Mood – Promoting Access to Collaborative Treatment (IMPACT)</i>		✓	✓	Healthcare Social Services
	<i>Collaborative Assessment and Management of Suicidality (CAMS)</i>		✓	✓	

		Best Available Evidence			
Intervene to lessen harms and prevent future risk	<i>Dialectical Behavioral Therapy</i>		✓	✓	
	<i>Attachment-Based Family Therapy</i>		✓		
	Treatment to prevent re-attempts				
	<i>ED Brief Intervention with Follow-up Visits</i>	✓			Healthcare
	<i>Active follow-up contact approaches</i>	✓	✓		
	<i>CBT for Suicide Prevention</i>				
	Postvention				
	<i>StandBy Response Service</i>		✓		Healthcare
	Safe messaging following a suicide				
	<i>Media Guidelines</i>	✓			Public Health

<sup>1</sup>This column refers to the lead sectors well positioned to bring leadership and resources to implementation efforts. For each strategy, there are many other sectors such as non-governmental organizations that are instrumental to prevention planning and implementing the specific programmatic activities.

## Overview

This technical package represents a select group of strategies based on the best available evidence to help communities and states sharpen their focus on prevention activities with the greatest potential to prevent suicide. These strategies include strengthening economic supports; strengthening access to mental health care; creating protective environments; promoting connectedness to protect against suicide; teaching coping and problem-solving skills; identifying and supporting people at-risk; and intervening to lessen harms and prevent future risk. The strategies represented in this package include those with a focus on preventing suicide from happening in the first place as well as approaches to lessen the immediate and long-term harms of suicidal behavior for individuals, families, communities, and society. The strategies in the technical package support the goals and objectives of the National Strategy for Suicide Prevention and the National Action Alliance for Suicide Prevention's priority to strengthen community-based prevention. Commitment, cooperation, and leadership from numerous sectors, including public health, education, justice, health care, social services, business/labor, and government can bring about the successful implementation of this package.

### What is a Technical Package?

A technical package is a compilation of a core set of strategies to achieve and sustain substantial reductions in a specific risk factor or outcome (Frieden, 2014). Technical packages help communities and states prioritize prevention activities based on the best available evidence. This technical package has three components. The first component is the **strategy** or the preventive direction or actions to achieve the goal of preventing suicide. The second component is the **approach**. The approach includes the specific ways to advance the strategy. This can be accomplished through *programs, policies, and practices*. The approaches included come primarily from studies based in the United States. The **evidence** for each of the approaches in preventing suicide or its associated risk factors is included as the third component. This package is intended as a resource to guide and inform prevention decision-making in communities and states.

### Preventing Suicide is a Priority

Suicide, as defined by the Centers for Disease Control and Prevention (CDC), is part of a broader class of behavior called *self-directed violence*. Self-directed violence refers to behavior directed at oneself that deliberately results in injury or the *potential* for injury (Crosby, Ortega, & Melanson, 2011). Self-directed violence may be *suicidal* or *non-suicidal* in nature. For the purposes of this document, we refer only to behavior where suicide is intended:

- **Suicide** is a death caused by self-directed injurious behavior with any intent to die as a result of the behavior.

- **Suicide attempt** is defined as a *non-fatal* self-directed and potentially injurious behavior with any intent to die as a result of the behavior. A suicide attempt may or may not result in injury.

**Suicide is highly prevalent.** Suicide presents a major challenge to public health in the United States and worldwide. It contributes to premature death, morbidity, lost productivity, and health care costs (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014). In 2014 (the most recent year of available death data), suicide was responsible for 42,773 deaths in the U.S., which is approximately one suicide every 12 minutes (Centers for Disease Control and Prevention, 2016d). In 2014, suicide ranked as the 10th leading cause of death and has been among the top 12 leading causes of death since 1975 in the U.S (Centers for Disease Control and Prevention, 2016d). Overall suicide rates have increased 24% from 1999 to 2014 (Curtin, Warner, & Hedegaard, 2016). Suicide is a problem throughout the life span; it is the second leading cause of death among those aged 10–19 years, also second among persons in their 20s and 30s; it is the fourth leading cause among persons in their 40s and seventh among persons in their 50s (Centers for Disease Control and Prevention, 2016d).

Suicides reflect only a portion of the problem (Crosby, Han, Ortega, Parks, & Gfroerer, 2011). Substantially more people are hospitalized as a result of nonfatal suicidal behavior (i.e. suicide attempts) than are fatally injured, and an even greater number are either treated in ambulatory settings (e.g., emergency departments) or not treated at all (Crosby, Han, et al., 2011). For example, during 2014, among adults aged 18 years and older, for every one suicide there were 9 adults treated in hospital emergency departments for self-harm injuries, 27 who reported making a suicide attempt, and over 227 who reported seriously considering suicide (i.e. ideation) (Ferdon et al., In press).

**Suicide is associated with several risk and protective factors.** Suicide, like other human behaviors, is complex with no single determining cause. Instead, suicide occurs in response to multiple biological, psychological, interpersonal, environmental and societal influences that interact with one another, often over time. The social-ecological model-- encompassing multiple levels of focus from the individual, relationship, community, and societal-- is a useful framework for viewing and understanding suicide risk factors identified in the literature (Dahlberg & Krug, 2002). Risk and protective factors for suicide exist at each level. For example, risk factors include:

- **Individual level:** History of depression and other mental illnesses, alcohol and drug abuse, previous suicide attempt, violence victimization, genetic and biological determinants, hopelessness
- **Relationship level:** High conflict or violent relationships, sense of isolation and lack of social support, family/loved one's history of suicide, financial and work stress
- **Community level:** Inadequate community connectedness, barriers to health care (e.g., lack of access to providers and medications)

- **Societal level:** Availability of lethal means of suicide, unsafe media portrayals of suicide, stigma associated with help-seeking and mental illness (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014).

It is important to recognize that the vast majority of individuals who are depressed or who have other risk factors noted, do *not* die by suicide. Furthermore, the relevance of each risk factor can vary by age, race, gender, sexual orientation, residential geography, and socio-cultural and economic status (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014).

Protective factors, or those influences that guard *against* the risk for suicide, can also be found across the different levels of the social-ecological model. Protective factors identified in the literature include: effective coping and problem solving skills, moral objections to suicide, strong and supportive relationships with partners, friends, and family; connectedness to school, community and other social institutions; availability of quality and ongoing physical and mental health care, and reduced access to lethal means (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014). These protective factors can either counter a specific risk factor or guard against a number of risks associated with suicide.

**Suicide is connected to other forms of violence.** Suicide and other forms of violence often share some of the same root causes (Butchart, Phinney, Check, & Villaveces, 2004; Klevens, Simon, & Chen, 2012). For example, in neighborhoods where there is low social cohesion, or where residents don't support and trust each other, people are at higher risk for suicide (Desai, Dausey, & Rosenheck, 2005) as well as perpetration of child maltreatment (Coulton, Crampton, Irwin, Spilsbury, & Korbin, 2007; Freisthler, Merritt, & LaScala, 2006), teen dating violence (Capaldi, Knoble, Shortt, & Kim, 2012), intimate partner violence (Pinchevsky & Wright, 2012), and youth violence (Sampson, Morenoff, & Gannon-Rowley, 2002). Additionally, a lack of economic opportunities and unemployment are associated with suicide (Luo, Florence, Quispe-Agnoli, Ouyang, & Crosby, 2011; Reeves et al., 2012), as well as perpetration of child maltreatment (D. Runyan, Wattam, Ikeda, Hassan, & Ramiro, 2002), intimate partner violence (Heise & Garcia-Moreno, 2002; Pinchevsky & Wright, 2012), sexual violence (Centers for Disease Control and Prevention, 2016c) and youth violence (Wilson, 2011). Other shared risk factors for suicide and violence occur at the individual level and include substance abuse, mental health problems, witnessing violence, and a lack of problem-solving skills (Centers for Disease Control and Prevention, 2016a, 2016c, 2016e; U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012).

Just as risk factors may be shared across suicide and violence, so too may protective factors overlap. For example, connectedness increases individual's and communities' resilience to suicide and other forms of violence, including connectedness to one's community (Basile, Hamburger, Swahn, & Choi, 2013; Borowsky, Hogan, & Ireland, 1997; Centers for Disease Control and Prevention, 2016b; Coulton et al.,

2007; Kleiman, Riskind, Schaefer, & Weingarden, 2012; Pinchevsky & Wright, 2012; Widome, Sieving, Harpin, & Hearst, 2008), school (Basile, Espelage, Rivers, McMahon, & Simon, 2009; Capaldi et al., 2012; Carter, McGee, Taylor, & Williams, 2007; DeGue et al., 2013; Hong, Kral, Espelage, & Allen-Meares, 2012; Losel & Farrington, 2012), family (Capaldi et al., 2012; Centers for Disease Control and Prevention, 2016a; Elgar, Craig, Boyce, Morgan, & Vella-Zarb, 2009; Maimon, Browning, & Brooks-Gunn, 2010; Resnick, Ireland, & Borowsky, 2004), caring adults (Capaldi et al., 2012; Losel & Farrington, 2012; Maimon et al., 2010), and pro-social peers (Capaldi et al., 2012; Losel & Farrington, 2012).

**The health and economic consequences of suicide are substantial.** Suicide and suicide attempts have far-reaching consequences for individuals, families, and communities (Dunne, McIntosh, & Dunne-Maxim, 1987; Mishara, 1995; National Action Alliance for Suicide Prevention: Suicide Attempt Survivors Task Force, 2014; National Action Alliance for Suicide Prevention: Survivors of Suicide Loss Task Force, 2015). By one conservative estimate, for every death by suicide six people are directly impacted (i.e. survivors). Based on this figure it is estimated that there are over 13 million survivors in the U.S. and unfortunately, survivorship itself is a risk factor for suicide (Crosby & Sacks, 2002). Research indicates that the health consequences of violence, including suicide, are also much more extensive than injury and death. Suicide attempt survivors (i.e. those with lived experience) may suffer long-term health and mental health consequences ranging from anger, guilt, and physical impairment, depending on the means and severity of the attempt (Chapman & Dixon-Gordon, 2007). Similarly, survivors of a loved one's suicide may experience ongoing pain and suffering including complicated grief (Mitchell, Kim, Prigerson, & Mortimer-Stephens, 2004), stigma, depression, anxiety, post-traumatic stress disorder, and increased risk of suicidal ideation and suicide (Julie Cerel, McIntosh, Neimeyer, Maple, & Marshall, 2014; Sudak, Maxim, & Carpenter, 2008).

The economic toll of suicide is immense as well. The total lifetime costs associated with nonfatal injuries and deaths caused by self-directed violence in 2013 were approximately \$93.5 billion after adjusting for under-reporting of suicide (Shepard, Gurewich, Lwin, Reed, & Silverman, 2016). The overwhelming burden of these costs results from lost productivity over the life course, with the average cost per suicide being over \$1.3 million (Shepard et al., 2016).

**Suicide can be prevented.** Despite the myths surrounding suicide, like most public health problems, suicide is preventable (U.S. Public Health Service, 1999). And while progress will continue to be made into the future, evidence for numerous programs, practices, and policies currently exists, and many programs are ready to be implemented now. Just as suicide is not caused by a single factor, research suggests that suicide will not be prevented by any single intervention taking place in any single setting (Silverman & Maris, 1995; U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012). Rather, suicide prevention is best achieved by a focus across the individual-, relationship-, family-, community, and societal-levels and across all sectors, private and public (e.g.,

business, public health, physical and behavioral healthcare, justice, education, labor) (National Action Alliance for Suicide Prevention, 2014; World Health Organization, 2014).

### **Assessing the Evidence**

This technical package includes programs, practices, and policies with evidence of impact on suicide or risk or protective factors for suicide. To be considered for inclusion in the technical package, the program, practice, or policy selected had to meet at least one of these criteria: a) meta-analyses or systematic reviews showing impact on suicide; b) evidence from at least one rigorous (e.g., randomized controlled trial [RCT] or quasi-experimental design) evaluation study that found significant preventive effects on suicide; c) meta-analyses or systematic reviews showing impact on risk or protective factors for suicide, or d) evidence from at least one rigorous (e.g., RCT or quasi-experimental design) evaluation study that found significant impacts on risk or protective factors for suicide. Finally, consideration was also given to the likelihood of achieving beneficial effects on multiple forms of violence; no evidence of harmful effects on specific outcomes or with particular subgroups; and feasibility of implementation in a U.S. context if the program, policy, or practice has been evaluated in another country.

Within this technical package, some approaches do not yet have research evidence demonstrating impact on rates of suicide but instead are supported by evidence indicating impacts on risk or protective factors for suicide (e.g., help-seeking, stigma reduction, depression, connectedness). In terms of the strength of the evidence, programs that have demonstrated effects on suicidal behavior (e.g., reductions in deaths, attempts) provide a higher-level of evidence, but the evidence base is not that strong in all areas. For instance, there has been less evaluation of community engagement and family programs on suicidal behavior. Thus, approaches in this package that have effects on risk or protective factors reflect the developmental nature of the evidence base and the use of the best available evidence at a given time.

It is also important to note that there is often significant heterogeneity among the programs, policies, or practices that fall within one approach or strategy area in terms of the nature and quality of the available evidence. Not all programs, policies, or practices that utilize the same approach (e.g., gatekeeper training) are equally effective, and even those that are effective may not work across all populations. Tailoring programs and more evaluation may be necessary to address different population groups. The examples provided are not intended to be a comprehensive list of evidence-based programs, policies, or practices for each approach, but rather illustrate models that have been shown to impact suicide or have beneficial effects on risk or protective factors for suicide. In practice, the effectiveness of the programs, policies and practices identified in this package will be strongly dependent on the quality of their implementation and the communities in which they are implemented. Implementation guidance to assist practitioners, organizations and communities will be developed separately.

### Context and Cross-Cutting Themes

The strategies and approaches that have been included in this technical package represent different levels of the social ecology, with efforts intended to impact the community and societal levels, as well individual and relationship levels. The strategies and approaches are intended to work in combination and reinforce each other to prevent suicide (see box below). The strategies are arranged in order such that those strategies hypothesized to have the greatest potential for broad public health impact on suicide are included first, followed by those that might impact more select populations (e.g., persons who have already made a suicide attempt).

**Comment [A]:** Can we just call this Promote Connectedness so it's more consistent with other strategy titles? Not sure why we have to say to protect against suicide.

Preventing Suicide	
Strategy	Approach
Strengthen economic supports	<ul style="list-style-type: none"><li>Strengthen household financial security</li><li>Housing stabilization policies</li></ul>
Strengthen access to mental health care	<ul style="list-style-type: none"><li>Coverage of mental health conditions in health insurance policies</li></ul>
Create protective environments	<ul style="list-style-type: none"><li>Reducing access to lethal means among persons at-risk of suicide</li><li>Organizational policies and culture</li><li>Community-based policies to reduce excessive alcohol use</li></ul>
Promote connectedness to protect against suicide	<ul style="list-style-type: none"><li>Peer norm approaches</li><li>Community engagement activities</li></ul>
Teach coping and problem-solving skills	<ul style="list-style-type: none"><li>Social-emotional learning</li><li>Parenting skill and family relationship approaches</li></ul>
Identify and support people at risk	<ul style="list-style-type: none"><li>Gatekeeper training</li><li>Screening combined with care management</li><li>Crisis intervention</li></ul>
Intervene to lessen harms and prevent future risk	<ul style="list-style-type: none"><li>Treatment for people at-risk of suicide</li><li>Treatment to prevent re-attempts</li><li>Postvention</li><li>Safe messaging following a suicide</li></ul>

The example programs, policies, and practices have been implemented within particular contexts. The social and cultural context of communities is critically important to take into account when selecting strategies and approaches. Practitioners in the field may be in the best position to assess the needs and strengths of their communities and work with community members to make decisions about the combination of approaches included here that are best suited to their context.

Suicide ideation, attempts, morbidity and mortality vary by gender, race/ethnicity, age, occupation, and other important population characteristics. Barriers to disclosure, help seeking, timely access to quality care, and ongoing support are profoundly complex and may also vary by population and community characteristics. Ideally, the availability of multiple approaches tailored to the economic, cultural, and environmental context of individuals and communities are desirable as they may increase the likelihood of removing barriers to supportive and effective care and provide opportunities to develop individual and community resilience. These culturally appropriate approaches can then be included in comprehensive strategies to maximize the public health impact on reducing suicide-related morbidity and mortality among individuals and within communities.

This package includes strategies where public health agencies are well positioned to bring leadership and resources to implementation efforts. It also includes strategies where public health can serve as an important collaborator (e.g., strategies addressing community and societal level risks), but where leadership and commitment from other sectors such as business/labor or health care is critical to implement a particular policy or program (e.g., workplace policies; screening combined with care management). The role of various sectors in the implementation of a strategy or approach in preventing suicide is described further in the section on *Sector Involvement*.

In the sections that follow, the strategies and approaches with the best available evidence for preventing suicide are described.

## Strengthen Economic Supports

### Rationale

Public health research suggests that some of the biggest impacts on health come from policies developed to improve socioeconomic conditions (Frieden, 2010). Downturns in the economy and increases in unemployment and home foreclosures are associated with increased rates of suicide (Fowler, Gladden, Vagi, Barnes, & Frazier, 2015; Luo et al., 2011). Policies that strengthen economic supports can help people stay in their homes, pay for necessities such as food and medical care, and get job training, among other things. In providing this support, stress and anxiety and the potential for a crisis situation may be reduced, thereby preventing suicide.

### Approaches

Economic and housing supports for individuals and families can be strengthened by improving policies that enhance financial security and stabilize housing for people, especially in times of economic need.

- **Strengthen household financial security.** Studies from the U.S. indicate that suicide rates increase during economic recessions marked by high unemployment rates, job losses, and economic instability and decrease during economic expansions and periods marked by low unemployment rates, particularly for working-age individuals 25 to 64 years old (Luo et al., 2011; Fowler et al., 2015).

### Potential Outcomes

- Reduced suicide rates
- Lower foreclosure rates
- Lower eviction rates
- Reduced emotional distress

### Evidence

There is evidence suggesting that strengthening household financial security and stabilizing housing can reduce suicide risk.

- **Strengthen household financial security.** An examination of variations in U.S. *unemployment benefit programs* across states demonstrated that the impact of unemployment on suicide was offset in those states that provided greater than average unemployment benefits (Cylus, Glymour, & Avendano, 2014). Another U.S. study examining the link between unemployment and suicide risk using monthly suicide data, length of unemployment, and job losses found that the duration of unemployment, as opposed to just the loss of job, predicted suicide risk (Classen & Dunn, 2012). Together, these results suggest that not only should state unemployment benefit programs be generous in their financial allocations, but also in their duration. **Other measures to**

**Comment [A]:** The rationale should focus on the strategy – strengthening economic supports – and how and why that might be beneficial in reducing suicide. As part of the rationale you can talk about how suicide relates to economic factors (e.g., historical data shows that suicide rates rise during periods of economic recessions and decreases during periods of economic expansion); how economic stressors (job loss, long periods of unemployment, reduced income, difficulty covering medical, food, housing expenses, etc.) increase risk for suicide and how buffering these risks can potentially protect against suicide. You cover this a

**Comment [A]:** Statement should be more along the lines of:

“There are a number of approaches that can help strengthen economic supports and buffer against the risk for suicide.”

Or

“Economic supports for individuals and families can be strengthened by targeting household financial security and ensuring stability in housing during periods of economic stress.”

**Comment [A]:** This would be a good introductory sentence to the rationale. For the two approaches, suggest saying something along the following lines:

**Strengthening household financial security** can reduce the risk for suicide by providing individuals with the necessary means to cover basic expenses and lessen the stress and hardship associated with a job loss or other unanticipated financial problems. The provision of unemployment benefits, livable wages, Temporary Assistance to Needy Families (TANF), medical benefits, and retirement and disability insurance to help cover the costs of basic necessities or to offset costs

strengthen household financial security (e.g., transfer payments related to retirement and disability insurance, unemployment insurance compensation, medical benefits, and other forms of family assistance) have also shown an impact on suicide. A study by Flavin and Radcliff (2009) examined the impact of states' per capita spending on transfer payments, medical benefits, and family assistance and total state spending on suicide rates between 1990-2000, controlling for a number of suicide risk factors (e.g., residential mobility, divorce rate, unemployment rate) at the state level. As per capita spending on total transfer payments, medical benefits, and family assistance increased there was an associated decrease in state suicide rates. Moreover, it wasn't spending in general that was associated with the reduction but spending on these types of assistance. In terms of lives saved, Flavin & Radcliff calculated the cost of reducing a state's suicide rate by a full point for the years studied. At the national level, an estimated 3,000 fewer suicides would occur per year nationwide if every state increased their per capita spending on these types of assistance by \$45 per year (Flavin & Radcliff, 2009).

- **Housing stabilization policies.** The *National Neighborhood Stabilization Program* was designed to help neighborhoods suffering from high rates of foreclosure and abandonment by slowing the deterioration of the neighborhoods and providing affordable housing options for low, moderate, and middle-income homebuyers. This program also offers financial assistance to eligible individuals for the purchase of a new home. Although this program has not been rigorously evaluated for its impact on suicide outcomes, it addresses foreclosure and eviction, which are risk factors for suicide. A longitudinal analysis of annual data on suicides and foreclosures demonstrated that as the proportion of foreclosed properties increased in U.S. states, so did the state suicide rate, particularly among working-aged adults (Houle & Light, 2014). Another study of data from 16 U.S. states participating in the National Violent Death Reporting System found that suicides precipitated by home foreclosures and evictions increased more than 100% from 2005 (before the housing crisis began) to 2010 (after it had peaked; Fowler et al. (2015)). Most of these suicides occurred prior to the actual loss of the decedent's home. These findings suggest that integrating suicide prevention resources, messaging, and referrals into financial, foreclosure, and move-out planning and counseling services may help to prevent suicide.

## Strengthen Access to Mental Health Care

### Rationale

While most people with mental health problems do not attempt or die by suicide (Olfson, Gerhard, Huang, Crystal, & Stroup, 2015; Owens, 2002), and risk conferred by mental illnesses differ (Arsenault-Lapierre, Kim, & Turecki, 2004; E. C. Harris & Barraclough, 1997; Tyrer, Reed, & Crawford, 2015), previous research indicates that mental illness is an important risk factor for suicide (E. C. Harris & Barraclough, 1998; World Health Organization, 2014). Studies suggest that up to 90% of people who die by suicide may have had a mental illness at the time of their deaths (Arsenault-Lapierre et al., 2004; Cavanagh, Carson, Sharpe, & Lawrie, 2003; Isometsa, 2001). State-level suicide rates have also been found to be correlated with general mental health measures such as depression (Lang, 2013; Mark, Shern, Bagalman, & Cao, 2007). Findings from the National Comorbidity Survey indicate that relatively few people in the U.S. with mental health disorders receive treatment for those conditions (Kessler et al., 2005). Lack of access to mental health care is one of the contributing factors related to the underuse of mental health services (Cunningham, 2009). Identifying ways to improve access to timely, affordable, and quality mental health care for people in need is a critical component to suicide prevention (World Health Organization, 2014). Apart from the treatment benefits, it can also serve to normalize help-seeking behavior and increase the use of such services.

### Approaches

One approach to strengthening access to mental health care is through the provision of mental health coverage in health insurance policies.

- **Coverage of mental health conditions in health insurance policies.** Federal and state laws include provisions for equal coverage of mental health services in health insurance plans that is on par with coverage for other health concerns (i.e., mental health parity). Benefits and services covered include such things as the number of visits, co-pays, deductibles, inpatient/outpatient services, prescription drugs, and hospitalizations. If a state has a stronger mental health parity law than the federal parity law, then insurance plans regulated by the state must follow the state parity law. Federal parity replaces the state law only in cases where the state law prevents the application of the federal parity law (e.g., includes coverage for some mental health conditions but not others). Equal coverage does not necessarily imply good coverage as health insurance plans vary in the extent to which benefits and services are offered to address various health conditions. Rather it helps to ensure that mental health services are covered on par with other health concerns.

### Potential Outcomes

- Increased utilization of mental health services

- Decreased symptoms of mental illnesses
- Decreased rates of suicide attempts
- Decreased rates of suicide

## Evidence

There is evidence suggesting that coverage of mental health conditions in health insurance policies can reduce risk factors associated with suicide and may directly impact suicide rates.

- **Coverage of mental health conditions in health insurance policies.** The National Survey of Drug Use and Health is a nationally representative survey of the U.S. population that provides data on substance use, mental health conditions, and services utilization. Using data from this survey, K. M. Harris, Carpenter, and Bao (2006) found that 12 months after states enacted *mental health parity laws*, self-reported use of mental healthcare services significantly increased. Moreover, subsequent research by Lang (2013) examined state mental health laws and suicide rates between 1990 and 2004 and found that mental health parity laws, specifically, were associated with an approximate 5% reduction in suicide rates. This reduction, in the 29 states with parity laws, equated to the prevention of 592 suicides per year and a cost savings of \$1.3-3.1 million per suicide prevented (Lang, 2013).

## Create Protective Environments

### Rationale

**Comment [A]:** Not sure if the additions I made to the rationale are too duplicative of info below. If so, go ahead and delete.

Prevention efforts that focus not only on individual behavior change (e.g., help-seeking, treatment interventions) but on changes to the environment can increase the likelihood of positive behavioral and health outcomes (Haddon, 1980). Creating environments that address risk and protective factors where individuals live, work, and play, can help prevent suicide (Dahlberg & Krug, 2002; U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012). For example, rates of suicide and suicide attempts are elevated in certain occupational groups (Han et al., 2016; McIntosh et al., 2016), therefore, changes to the organizational culture in these occupations, by way of implementation of supportive policies or even physical modifications to the workplace environment, can demonstrate that good health and mental health are valued and that stigma and other risk factors for suicide, are not (K. L. Knox et al., 2010; National Action Alliance for Suicide Prevention Workplace Task Force, 2015). Similarly, changing the availability of and access to common suicide risk factors in the environment such as bridges, alcohol, medications, or firearms, can reduce suicide rates, particularly in times of crisis (Beautrais, Gibb, Fergusson, Horwood, & Larkin, 2009; Crosby, Espitia-Hardeman, Ortega, & Lozano, 2013; Kaplan et al., 2013; Miller, Warren, Hemenway, & Azrael, 2015; C. W. Runyan et al., 2016).

### Approaches

The current evidence suggests three promising approaches for creating environments that protect against suicide.

- **Reducing access to lethal means among persons at-risk of suicide.** Means of suicide such as firearms, hanging/suffocation, or jumping from heights provide little opportunity for rescue and, as such, have high case fatality rates (e.g., about 85% of people who use a firearm in a suicide attempt will die from the injury). Research also indicates that 1) the interval between thinking about and attempting suicide can be as short as 5 or 10 minutes (Deisenhammer et al., 2009; Simon et al., 2001) and 2) that people tend *not* to substitute a different method when a highly lethal method is unavailable or difficult to access (Hawton, 2007; Yip et al., 2012). Therefore, increasing the time interval between the thought and the suicide attempt, for example, by making it more difficult to access lethal means, can be lifesaving. The following are examples of approaches reducing access to lethal means for persons at-risk of suicide:
  - *Intervening at Suicide Hotspots.* Suicide hotspots, or places where suicides may take place relatively easily, include tall structures (e.g., bridges and cliffs), railway tracks, and isolated locations such as parks. Efforts to prevent suicide at these locations include

erecting barriers to prevent jumping and installing signs and telephones to encourage individuals who are considering suicide, to seek help (Cox et al., 2013).

- *Safe Storage Practices.* Safe storage of medications, firearms, and other household products can reduce the risk for suicide by separating individuals who may be vulnerable and/or impulsive from easy access to lethal means. Such practices may include education and counseling around storing firearms--locked in a secure place (e.g., in a gun safe or lock box), unloaded and separate from the ammunition--and keeping medicines in a locked cabinet or other secure location away from people who may be at risk or who have made prior attempts (Rowhani-Rahbar, Simonetti, & Rivara, 2016; C. W. Runyan et al., 2016).
- **Organizational policies and culture** that promote protective environments may be implemented in places of employment. Such policies and cultural values may promote prosocial behavior (e.g., asking for help), skill building, changing social norms, referral and access to helping services (e.g. mental health, substance abuse treatment, financial counseling), and encourage leadership support from the top down. Such policies and cultural shifts can positively impact organizational climate and morale and help prevent suicide and its related risk factors (e.g. depression, social isolation) (National Action Alliance for Suicide Prevention Workplace Task Force, 2015).
- **Community-based policies to reduce excessive alcohol use.** Research studies in the United States have found that greater alcohol availability is positively associated with alcohol-involved suicides (Escobedo & Ortiz, 2002; Giesbrecht et al., 2015). Policies to reduce excessive alcohol use broadly include zoning to limit alcohol outlet locations and density, taxes on alcohol, and bans on the sale of alcohol for individuals under the legal drinking age. These policies are important because acute alcohol use has been found to be associated with more than one-third of suicides and approximately 40% of suicide attempts (Cherpitel, Borges, & Wilcox, 2004).

### Potential Outcomes

- Increase in safe storage of means
- Reduction in suicide attempts
- Reduction in suicide deaths
- Increase in help-seeking
- Reduction in alcohol-related suicide deaths

### Evidence

The evidence for the effectiveness of means restriction and other ways to establish protective environments is some of the strongest in the field (Zalsman et al., 2016), as described below.

- **Reducing access to lethal means among persons at-risk of suicide.** A meta-analysis examining the impact of *suicide hotspot interventions* implemented in combination or in isolation, both in the U.S. and abroad, found associated reduced rates of suicide (Cox et al., 2013; Pirkis et al., 2015). For example, after erecting a barrier on the Jacques-Cartier bridge in Canada, the suicide rate from jumping from the bridge decreased from about 10 suicide deaths per year to about 3 deaths per year (Perron, Burrows, Fournier, Perron, & Ouellet, 2013). Moreover, the reduction in suicides by jumping was sustained even when all bridges and nearby jumping sites were considered, suggesting little to no displacement of suicides to other jumping sites (Perron et al., 2013). Further evidence for the effectiveness of bridge barriers was demonstrated by a study examining the impact of the *removal* of safety barriers from the Grafton Bridge in Auckland, New Zealand. After removal of the barrier, sadly, both the number and rate of suicide increased fivefold (Beautrais, 2001; Beautrais et al., 2009).

Another form of means reduction involves implementation of *safe storage practices*. In a case-control study of firearm-related events identified from 37 counties in Washington, Oregon, and Missouri, and from 5 trauma centers, Grossman et al. (2005) found that storing firearms unloaded, separate from ammunition, in a locked place and/or secured with a safety device was protective of suicide attempts among adolescents. Further, a recent systematic review of clinic and community-based education and counseling interventions suggested that the provision of safety devices significantly increased safe firearm storage practices compared to counseling alone or compared to the provision of economic incentives to acquire safety devices on one's own (Rowhani-Rahbar et al., 2016).

Another program, *The Emergency Department Counseling on Access to Lethal Means (ED CALM)*, trained psychiatric emergency clinicians in a large children's hospital to provide lethal means counseling and safe storage boxes to parents of patients under age 18 receiving care for suicidal behavior. In a pre-post quality improvement project, Runyan et. al (2016) found that at post-test 76% (of the 55% of parents followed up, n=114) reported that all medications in the home were locked up as compared to fewer than 10% at the time of the initial emergency department visit. Among parents who indicated the presence of guns in the home at pre-test (i.e. 67%), all (100%) reported guns were currently locked up at post-test (C. W. Runyan et al., 2016).

- **Organizational policies and culture.** *Together for Life* is a workplace program of the Montreal Police Force implemented to address suicide among officers. Policy and program components were designed to foster an organizational culture that promoted mutual support and solidarity among all members of the Force. The program included training of supervisors, managers and all units to improve competencies in identifying suicidal risk and to improve use and awareness of existing resources. The program also included an education campaign to improve awareness and help-seeking (Mishara & Martin, 2012). Police suicides were tracked over 12 years and

compared to rates in the control city of Quebec. The suicide rate in the intervention group decreased significantly by 78.9% to a rate of 6.42 suicides per 100,000 population per year compared to an 11% increase in the control city (rate: 29.0 per 100,000) (Mishara & Martin, 2012).

Another example of this approach is the *United States Air Force Suicide Prevention Program (AFSPP)*. AFSPP included 11 policy and education initiatives and was designed to change the culture of the Air Force surrounding suicide. The program uses leaders as role models and agents of change, establishes expectations for behavior related to awareness of suicide risk, develops population skills and knowledge (i.e., education and training), and investigates every suicide (i.e., outcomes measurement). The program represents a fundamental shift from viewing suicide and mental illness solely as medical problem and instead sees them as larger service-wide problems impacting the whole community (K. L. Knox, Litts, Talcott, Feig, & Caine, 2003). Using a time-series design to examine the impact of the AFSPP program on various violence-related outcomes, researchers found that the program was associated with a 33% relative risk reduction in suicide (K. L. Knox et al., 2003). The program was also associated with relative risk reductions in related outcomes including moderate and severe family violence (30% and 54%, respectively), homicide (51%), and accidental death (18%) (K. L. Knox et al., 2003). A longitudinal assessment of the program over the period 1981 to 2008 (16 years before the 1997 launch of the program and 11 years post-launch) found significantly lower rates of suicide after the program was launched than before (K. L. Knox et al., 2010). These effects were sustained over time, except in 2004, which the authors found was associated with less rigorous implementation in that year than in the other years (K. L. Knox et al., 2010).

- **Community-based policies to reduce excessive alcohol use.** While multiple policies to limit alcohol use exist, several studies on alcohol outlet *density*, specifically, suggest that measures to reduce alcohol outlet density can potentially reduce alcohol-involved suicides. Additionally, a longitudinal analysis of alcohol outlet density, suicide mortality, and hospitalizations for suicide attempts over 6 years in 581 California zip codes indicated that the density of bars, specifically, is related to suicide and suicide attempts, particularly in rural areas (Johnson, Gruenewald, & Remer, 2009).

## Promote Connectedness to Protect Against Suicide

### Rationale

Sociologist, Emile Durkheim theorized in 1897 that weak social bonds, i.e. lack of connectedness, are among the chief causes for suicidality (Durkheim, 1897/1951). *Connectedness* is the degree to which an individual or group of individuals are socially close, interrelated, or share resources with others (Centers for Disease Control and Prevention, 2009). Social connections can be formed within and between multiple levels of the social ecology (Dahlberg & Krug, 2002), for instance between individuals (e.g. peers, neighbors, co-workers), families, schools, neighborhoods, workplace, faith communities, cultural groups, and society as a whole. Related to connectedness, *social capital* refers to a sense of trust in one's community and neighborhood, social integration, and also the availability and participation in social organizations (Beyer, Layde, Hamberger, & Laud, 2015; Muennig, Cohen, Palmer, & Zhu, 2013). Many ecological cross-sectional and longitudinal studies have examined the impact of aspects of social capital on depression symptoms, depressive disorder, mental health more generally, and suicide. While the evidence is still being built the pattern is towards an inverse association between social capital measured by social trust, community/ neighborhood engagement, and improved mental health. Connectedness and social capital together can serve to protect against suicidal behaviors by decreasing isolation, encouraging adaptive coping behaviors, increasing belongingness, personal value and worth all of which helps individuals to build resilience in the face of adversity. Connectedness can also provide individuals with better access to formal supports and resources, mobilize communities to meet the needs of its members and provide collective primary prevention activities to the community as a whole (Centers for Disease Control and Prevention, 2009).

### Approaches

Promoting connectedness among individuals and within communities through modeling peer norms and enhancing community engagement can protect against suicide.

- **Peer norm approaches** seek to normalize prosocial behaviors/protective factors for suicide such as help-seeking, reaching out and talking to trusted adults, and peer connectedness. These approaches typically target youth and are delivered in school settings but can also be implemented in community settings.

- **Community engagement activities.** Community engagement is an aspect of social capital. Community engagement approaches may involve residents participating in a range of activities, including religious activities, community clean-up and greening activities, and physical exercise. These activities provide opportunities for residents to become more involved in the community and to connect with other community members, organizations, and resources, resulting in enhanced overall physical health, reduced stress, and decreased depressive symptoms, thereby reducing risk of suicide.

### Potential Outcomes

- Reduction in maladaptive coping attitudes and behaviors
- Increase in healthy coping attitudes and behaviors
- Increase in referrals for youth in distressed
- Increase help-seeking behaviors
- Positive perception of adult support

### Evidence

Current evidence suggests that peer norm approaches and community engagement can reduce risk factors associated with suicidal behaviors.

- **Peer norm approaches.** Evaluations show that programs such as *Sources of Strength* can improve school norms and beliefs about suicide that are created and disseminated by student peers. In a randomized controlled trial of *Sources of Strength* conducted with 18 high-schools (6 metropolitan, 12 rural), Wyman et al. (2010) found that the program improved peer leaders' adaptive norms regarding suicide, their connectedness to adults, and school engagement. Peer leaders were also more likely than controls to refer a suicidal friend to an adult. Among students, the intervention increased perceptions of adult support for suicidal youths and the acceptability of seeking help. Perception of adult support increased most in students with a history of suicidal ideation. Finally, trained peer leaders also reported a greater decrease in maladaptive coping attitudes compared with untrained leaders (Wyman et al., 2010).
- **Community engagement activities.** A vacant lot greening initiative was undertaken in Philadelphia between 1999 and 2008. Local residents and community members worked together to green 4,436 lots (or 7.8 million square feet) in 4 areas of the city. Researchers found significant associated reductions in community residents' self-reported stress levels and engagement in more physical exercise than residents in control vacant lot areas. Other benefits included reductions in firearm assaults and vandalism (Branas et al., 2011).

## Teach Coping and Problem-Solving Skills

### Rationale

Building life skills prepares individuals to successfully tackle every day challenges and adapt to stress and adversity. Life skills encompasses many concepts, but most often include coping and problem-solving skills, conflict resolution, and critical thinking. Life skills are important in shielding individuals from suicidal behaviors (World Health Organization, 2014). Suicide prevention programs that focus on life and social skills training are drawn from social cognitive theories (Bandura, 1986), surmising that individuals who engage in suicidal behavior is attributed to either direct learning, modeling, and environmental and individual (e.g. hopelessness) characteristics. The literature linking life skills and suicide is robust--- The inability to employ adequate coping strategies to cope with immediate stressors or identify and find solutions for problems have been characterized among suicide attempters (Pollock & Williams, 2004). Treatments that include bolstering problem skills (Goldsmith, Pellmar, Kleinman, & Bunney, 2002) and include problem-solving techniques (Ghahramanlou-Holloway, Bhar, Brown, Olsen, & Beck, 2012; Townsend et al., 2001) appear to reduce suicidal ideation and attempts more effectively. Prevention programs focused on teaching these skills target youth, parents and families and have been used with both universal and at-risk populations. While many do not target suicidal behaviors directly, these programs strive to train youth and parents important life skills to offset the underlying vulnerabilities that contribute to engaging in high risk behaviors early in life.

### Approaches

Current evidence provides support for the following two approaches:

- **Social emotional learning programs** focus on developing and strengthening communication and problem-solving skills, emotion regulation, conflict resolution, help seeking and coping skills. These approaches address a range of risk and protective factors for suicidal behavior. They provide children and youth with skills to resolve problems in relationships, school, and with peers, and help youth to address other negative influences (e.g., substance use) associated with suicide. These approaches are typically delivered to all students in a particular grade or school, although some programs also focus on groups of students considered to be at high-risk for suicide. Opportunities to practice and reinforce skills are an important part of programs that work (Herman, Borden, Reinke, & Webster-Stratton, 2011).
- **Parenting skill and family relationship programs** are designed to strengthen parenting skills, enhance positive parent-child interactions, and improve children's behavioral and emotional skills and abilities. Several parenting and family relationship programs have been shown in rigorous evaluations to improve resilience and reduce risk factors for various behaviors, including

ones closely related to suicide, such as depression, internalizing behaviors, and substance abuse (M. S. Knox, Burkhart, & Hunter, 2010).

### Potential Outcomes

- Reduction in suicide attempts and suicide ideation
- Enhanced knowledge of risk and protective factors associated with suicide
- Reduction in suicide risk behaviors (i.e., depression, anxiety, conduct problems, substance abuse)
- Improve and normalize help-seeking behavior
- Enhance social competence and emotional regulation skills
- Enhance problem-solving and conflict management skills

### Evidence

There are several programs with evidence that support teaching social, emotional and parenting skills to reduce suicidal behaviors and associated risk factors.

- **Social emotional learning programs.** The *Youth Aware of Mental Health Program (YAM)* is a program developed for teenagers that uses interactive dialogue and role-playing to teach adolescents about the risk and protective factors associated with suicide (including knowledge about depression and anxiety) and enhances their problem-solving skills for dealing with adverse life events, stress, school and other problems. The program includes 3 hours of role-play sessions and interactive workshops combined with a booklet that students can keep, educational posters displayed in classroom, and interactive lectures about mental health at the beginning and end of the program (Wasserman et al., 2014). In a cluster-randomized controlled trial of YAM conducted across 10 European Union countries and 168 schools, students participating in the YAM program were significantly less likely to have an incident suicide attempt (OR 0.45, 95%CI 0.24–0.85;  $p=0.014$ ) and severe suicidal ideation (0.50, 0.27-0.92;  $p=0.025$ ) at the 12-month follow-up compared to the control group. Additionally, related to severe suicide ideation, in the YAM group absolute risk fell by 0.50% and RR fell by 49.6% (Wasserman et al., 2014).

*Signs of Suicide (SOS)* is another school-based prevention program for students aged 13-17. The program includes guided classroom discussions about suicide and depression. As part of the program, students are screened for depression and suicide risk and referred for professional help as indicated. The program is designed to increase knowledge about suicide and risk factors associated with suicidal behavior as well as improve and normalize help-seeking behavior (Schilling, Aseltine, & James, 2016). In a randomized controlled trial, SOS was shown to reduce self-reported suicide attempts at 3-months post intervention among

participating students compared to control students. The SOS program also increased students' knowledge of how to get help for themselves or friends for depression and/or suicidal thoughts, and favorable attitudes toward help-seeking. SOS participants with a lifetime history of suicide attempt were also less likely to report planning a suicide in the 3 months following the program compared to lower-risk participants (Schilling et al., 2016).

Finally, the *Good Behavior Game (GBG)* is a classroom-based program for elementary school children aged 6-10; it represents an example of upstream suicide prevention programming. The program uses a team-based behavior management strategy that promotes good behavior by setting clear expectations for good behavior and consequences for maladaptive behavior. The goal of the GBG is to create an integrated classroom social system that is supportive of all children being able to learn with little aggressive or disruptive behavior (Wilcox et al., 2008). In an outcome evaluation of the GBG, first graders assigned to GBG reported half the adjusted odds of suicidal ideation and suicide attempts. The beneficial effect of the program was consistent for suicidal ideation regardless of whether baseline covariates were included. The GBG effect on attempts was less robust in some adjusted models including caregiver mental health. In the second cohort of GBG students, neither suicidal ideation nor suicide attempts were significantly different between GBG and the control interventions (Wilcox et al., 2008). This finding likely arose due to the lack of implementation fidelity and pointed to the need for GBG to be delivered with precision, consistency, and teacher support. GBG was also found to be associated with reduced risk of later substance abuse, a risk factor for suicide (Kellam et al., 2008).

- **Parenting skill and family relationship programs.** Parenting and family skills training approaches have shown promising impacts in preventing key risk factors associated with suicide. For example, the *Incredible Years (IY)* is a comprehensive group training program for parents, teachers and children designed to reduce conduct and substance abuse problems, two important suicide risk factors, in youth by improving protective factors such as responsive and positive parent-teacher-child interactions and relationships, emotion self-regulation and social competence (all protective factors for suicide) (Herman et al., 2011). The program includes 9- 20 sessions offered in community-based settings (e.g., religious, recreation centers, mental health treatment centers, and hospitals). Several studies have demonstrated the effect of the IY program on reducing internalizing symptoms, such as anxiety and depression, and child conduct problems (C. H. Webster-Stratton, Reid, & Beauchaine, 2011; Webster-Stratton, Jamila Reid, & Stoolmiller, 2008). The program is also associated with improved problem-solving and conflict management; these skills were maintained at 1-year follow-up (Reid, Webster-Stratton, & Hammond, 2003; C. Webster-Stratton & Hammond,

1997; C. Webster-Stratton, Reid, & Hammond, 2001). The program demonstrated greater benefits as the dosage of the intervention increased (Herman et al., 2011).

Additionally, *Strengthening Families 10-14* is a program that involves sessions between parents, youth, and family with the goal of improving parents' skills for disciplining, managing emotions and conflict, and communicating with their children; promoting youths' interpersonal and problem-solving skills; and creating family activities to build cohesion and positive parent-child interactions. The premise of the program is that developing these skills for both parents and children will reduce internalizing behavior and adolescent substance abuse, two important risk factors for suicide (Spoth, Gyll, & Day, 2002). *Strengthening Families* has been shown to decrease externalizing behaviors, alcohol use, and drug use among youth participants and reductions in depression, alcohol use, and drug use among participating families (Spoth et al., 2002).

## Identify and Support People At-Risk

### Rationale

In order to decrease suicide, attention to people at increased or high risk is necessary as these individuals tend to experience suicidal behavior at higher than average rates. These vulnerable or disadvantaged populations include, but are not limited to, individuals with lower socio-economic status or who are living with a mental health problem; people who have attempted suicide previously, individuals who are institutionalized, have been victims of violence, or are homeless; and members of certain ethnic minority groups. Supporting these vulnerable groups requires proactive case finding along with access to, and retention in, mental health services. Finding effective ways of identifying at-risk or vulnerable groups, customizing services to make them accessible and maintaining care remain key challenges. For example, simply improving services does not guarantee that those services will be used by those most in need of them, nor will it necessarily increase the number of people who follow treatments that are recommended. People who are disadvantaged face social and economic issues that may adversely affect their ability to respond to the treatments or advice that are offered.

### Approaches

The following three approaches focus on identifying and supporting people at increased risk.

- **Gatekeeper training** is designed to train teachers, coaches, providers and others in the community to identify people who may be at risk of suicide and to respond effectively, including facilitating treatment seeking and support services. Gatekeeper training is typically implemented in schools to identify at-risk youth and within health care settings to identify adults (and youth).
- **Screening combined with care management and overall continuity of care** has been used in primary care and behavioral health care settings to assure that people who may be at high-risk of suicide are identified and receive ongoing treatment as needed, particularly after inpatient discharge and other transitions within the healthcare system so they don't 'slip through the cracks'. These approaches typically employ screening for depression and/or suicide combined with collaborative treatment planning between patients and their providers and patient follow-up.
- **Crisis intervention.** These approaches provide support and referral services, typically by connecting a person in crisis (or a friend or family member of someone at-risk) to trained volunteers and/or professional staff via telephone hotline, online chat, or text messaging. Crisis intervention approaches are intended to impact key risk factors for suicide, including feelings of depression, hopelessness, and subsequent mental health care utilization. Like means reduction,

crisis interventions can put space or time between an individual who may be considering suicide and harmful behavior.

### Potential Outcomes

- Reduction in suicide attempts
- Reduction in suicide deaths
- Increased identification of individuals at-risk for suicidal behavior
- Increased at-risk individuals in treatment
- Increased community members trained to identify at-risk individuals
- Increased referrals for health care

### Evidence

There is evidence that community gatekeeper programs are successful in reducing suicides and suicide attempts but the efforts must be maintained (Substance Abuse and Mental Health Services Administration, 2014). However, there is limited evidence for effectiveness screening programs, but at the same time, standard principles for public health screening make them promising (Pena & Caine, 2006). The number of studies evaluating crisis intervention services is limited, but a few studies do indicate that those who use the hotline services have decreased suicidal thoughts and behavior.

- **Gatekeeper training.** One example of gatekeeper training is the *Mental Health First Aid (MHFA)* program. This program is designed for the lay public and consists of three weekly sessions of three hours each. Participants learn the symptoms of people in mental health crises and/or in the early stages of mental health problems (i.e., those experiencing suicidal thoughts and behavior, acute stress reaction, panic attacks and acute psychotic behavior, and depression, anxiety, and psychotic disorders), possible risk factors, and where and how to get evidence-based effective help (Kitchener & Jorm, 2004). In a randomized controlled trial of 300 participants of *MHFA*, the intervention group reported greater confidence in providing help to others, greater likelihood of advising people to seek professional help, improved concordance with health professionals about treatments, and decreased stigmatizing attitudes. Additionally, the intervention resulted in improved mental health of the participants themselves. All results were statistically significant at  $p < .05$ . (Kitchener & Jorm, 2004). Additional research rigorously evaluating *MHFA* for its impact on the first aid recipients themselves and suicidal behavior is needed (Kitchener & Jorm, 2006).

Gatekeeper training has also been a core part of all *Garret Lee Smith (GLS) Suicide Prevention Program* which is in place in 49 states and 48 tribes. A multi-site evaluation assessed the

connection between community gatekeeper training and a reduction of suicide attempts and deaths by comparing the change in suicide mortality rates and nonfatal suicidal behavior among the population aged 10-24 in counties implementing *GLS* trainings, with the trajectory observed in similar counties that did not implement these trainings. Counties implementing *GLS* trainings had significantly lower youth suicide rates the year following the training implementation (-1.07,  $p=.03$ ) (Walrath, Garraza, Reid, Goldston, & McKeon, 2015). This finding represents a decrease of 1 suicide death per 100,000 10 to 24 year olds or the avoidance of approximately 237 deaths in this age group between 2007 and 2010. Counties implementing *GLS* program activities also had significantly lower suicide attempt rates among youths 16 to 23 years of age in the year following implementation of the *GLS* program than did similar counties that did not implement *GLS* program activities (4.9 fewer attempts per 1000 youths [95% CI, 1.8-8.0 fewer attempts per 1000 youths];  $p = .003$ ; (Godoy Garraza, Walrath, Goldston, Reid, & McKeon, 2015)). More than 79 000 suicide attempts may have been averted during the period studied following implementation of the *GLS* program.

- **Screening combined with care management and overall continuity of care.** The *Henry Ford Perfect Depression Care* program was the pre-cursor to *Zero Suicide*, and its overall goal was to eliminate suicide. More broadly, though, the aim was to completely redesign depression care delivery to achieve breakthrough improvement in quality and safety by focusing on six aims: effectiveness, safety, patient centeredness, timeliness, efficiency, and equity among patients. The program developed concrete measures to assess progress on each of these aims and began with screening and assessment of each patient for suicide risk with coordinated continuous follow-up care system wide (C. E. Coffey, 2006). An examination of the impact of the *Henry Ford Perfect Depression Care (Pre-cursor to Zero Suicide)* program found that there was a dramatic and statistically significant decrease in the rate of suicide between the baseline years prior to the intervention (1999 and 2000) to the intervention years (2002-2009). During this time period, the suicide rate fell 82% (C. E. Coffey, 2006; C. E. Coffey, Coffey, & Ahmedani, 2013). Further, suicide rates also declined among HMO members who participated in targeted suicide prevention efforts and received mental health specialty services. However, for those HMO members who accessed only general medical services as opposed to specialty mental health services, the suicide rate increased (M. Coffey, Coffey, & Ahmedani, 2015).
- **Crisis intervention.** Suicide prevention hotlines are one way to provide crisis intervention. In an evaluation of the effectiveness of the *National Suicide Prevention Lifeline (NSPL)* to prevent suicide, 1,085 suicidal individuals who called the hotline completed a standard risk assessment for suicide, and 380 of those completed a follow-up assessment between 1 and 52 days after the initial assessment. Researchers found that over half of the initial sample were seriously considering suicide when they called, and they had a plan for their suicide. Researchers also

found that participants experienced significant decreases in suicidality over the course of the telephone session, and that levels of hopelessness and psychological pain continued to decrease after their initial call (Gould, Kalafat, Harrismunfakh, & Kleinman, 2007).

In another study, this time employing a randomized controlled trial, Gould, Cross, Pisani, Munfakh, and Kleinman (2013) assessed the impact of the *Applied Suicide Intervention Skills Training (ASIST)*, a widely implemented training program that helps hotline counselors, emergency workers, and other gatekeepers to identify and connect with suicidal individuals, understand their reasoning for living and dying, and assist with safely connecting those in need to available resources. The training was evaluated across the NSPL network of hotlines over the period 2008-2009. Using data from 1,410 suicidal individuals who called 17 Lifeline centers, researchers found that compared to callers who spoke to counselors that received the usual care training, individuals who spoke with counselors trained in *ASIST* were significantly more likely to feel less depressed, less suicidal, less overwhelmed, and more hopeful by the end of their call to the hotline. Counselors trained in *ASIST* were also more skilled at keeping callers on the phone longer and establishing a connection with them. However, training in *ASIST* did not result in more comprehensive suicide risk assessments than usual care training (Gould et al., 2013).

## Intervene to Lessen Harms and Prevent Future Risk

### Rationale

Individuals who have experienced mental health challenges, suicidal ideation, and/or who have made suicide attempts and/or have engaged in non-suicidal self-injury are at increased risk of suicide (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012). Risk of suicide can also increase among those who have lost a friend, family member, co-worker, or other acquaintance to suicide (Pitman, Osborn, King, & Erlangsen, 2014). Exposure to sensationalized or uninformed reporting regarding on suicide may heighten the risk of suicide among vulnerable individuals and can inadvertently contribute to suicide contagion (Etzersdorfer & Sonneck, 1998; Niederkrotenthaler & Sonneck, 2007).

### Approaches

A broad array of approaches to lesson harms and reduce future risk of suicide among those at increased risk include the provision of mental health care and improved continuity of care, improving linkage to care through active post-discharge planning and follow-up that decreases barriers to ongoing therapeutic support, increasing connectedness to supportive others, addressing bereavement, and framing communications to emphasize resilience, decrease negative affect, and to prevent contagion.

- **Treatment for people at-risk of suicide** typically includes various forms of psychotherapy delivered by licensed providers to help individuals with mental health problems and other risk factors for suicide with problem-solving, impulsivity and emotion regulation.
- **Treatment to prevent re-attempts.** These approaches typically include follow-up contact and use diverse modalities (e.g., home visits, mail, telephone, e-mail) to engage recent suicide attempt survivors in continued treatment to prevent re-attempts. Treatment may focus on improved coping skills, mindfulness, and other emotional regulation skills, and may include case management home visits to increase adherence to treatment and continuity of care; and one-on-one interpersonal therapy and/or group therapy. Approaches that engage and connect attempters to peers and providers are especially important because many attempters do not present to aftercare; 12%-25% reattempt within a year, and 3%-9% of attempt survivors die by suicide within 1 to 5 years of their initial attempt (Inagaki et al., 2015)
- **Postvention** approaches are implemented *after* a suicide has taken place and may include debriefing sessions, counseling, and/or bereavement support groups for surviving friends and family members/loved ones. These programs have not typically been evaluated for their impact on suicide or suicidal behavior but may reduce survivors' guilt, feelings of depression, and complicated grief (Szumilas & Kutcher, 2011).

- **Safe messaging following a suicide.** The manner in which information on a recent suicide is communicated to the public (e.g. school assemblies, mass media, social media) can heighten the risk of suicide among vulnerable individuals and can inadvertently contribute to suicide contagion. Therefore, responsible and safe reporting may help prevent suicide and/or suicide contagion.

### Potential Outcomes

- Reduction in mental health-related sequelae
- Increase connectedness
- Improved coping skills
- Improved messaging following suicide
- Reduction in re-attempts

### Evidence

The evidence addressing strategies to lesson harm and prevent future risk of suicide includes the evaluation of effects of specific approaches on risk and protective factors as well as suicide-related mortality. However, because the evaluation of suicide-related mortality requires large sample sizes and extended follow-up, much of the evidence in this area primarily focuses on risk and protective factors.

- **Treatment for people at-risk of suicide.** There are a number of treatments with evidence of impact on risk and protective factors for suicide. One example is the *Improving Mood – Promoting Access to Collaborative Treatment (IMPACT)* program. IMPACT aims to prevent suicide among older primary care patients by reducing suicide ideation and depression in primary care settings. It facilitates the development of a therapeutic alliance, a personalized treatment plan that includes patient preferences, as well as proactive follow-up (biweekly during an acute phase and monthly during continuation phase) by a depression care manager (Hunkeler et al., 2006). The program has been shown to significantly improve quality of life, and to reduce functional impairment, depression and suicidal ideation over 24-months of follow-up (Hunkeler et al., 2006; Unutzer et al., 2006) relative to patients who received care as usual.

Another example is *Collaborative Assessment and Management of Suicidality (CAMS)*, which is a therapeutic approach for suicide-specific assessment and treatment of patient's suicide risk. This flexible approach can be used across treatment settings and clinician theoretical orientations and involves the clinician and patient working together in an interactive assessment process to develop patient-specific treatment plans. CAMS sessions are collaborative and involve constant

**Comment [A]:** The write-up of the evidence for this strategy needs to follow the format used in the other sections of the TP. I modified the write-up for the first approach to illustrate the format. You will need to do something similar for the second approach.

patient about what is and is not working with the ultimate goal of enhancing the therapeutic alliance and increasing treatment motivation in the suicidal patient. CAMS been tested and supported in 6 correlational studies (Jobes, 2012), in a variety of inpatient and outpatient settings and in one RCT with several additional RCTs under way. CAMS has been associated with significant improvements in suicidal ideation, overall symptom distress, and feelings of hopelessness at 12 month follow-up among a community-based sample of suicidal outpatients. (Comtois et al., 2011).

Other examples include *Dialectical Behavioral Therapy (DBT)* and *Attachment-Based Family Therapy (ABFT)*. DBT is a multicomponent therapy for individuals at high risk for suicide and who may struggle with impulsivity and emotional regulation. The components of DBT include individual therapy, group skills training, between-session telephone coaching and a therapist consultation team. In a randomized controlled trial of women with recent suicidal or self-injurious behavior, those receiving DBT were half as likely to make a suicide attempt at two-year follow-up than women receiving community treatment (23% vs 46%), required less hospitalization for suicide ideation, and had lower medical risk across all suicide attempts and self-injurious acts combined (Linehan et al., 2006).

ABFT is a program for adolescents aged 12-18 and is designed to treat clinically diagnosed major depressive disorder, eliminate suicidal ideation, and reduce dispositional anxiety (Diamond et al., 2010). A randomized controlled trial of ABFT found that suicidal adolescents assigned to ABFT experienced significantly greater improvement in suicidal ideation over 24 weeks of follow-up than did adolescents assigned to enhanced usual care (-4.37 vs. -2.34;  $p = .001$ ;  $d=0.97$ ). Additionally, a higher percentage of ABFT participants reported no suicidal ideation in the week prior to assessment at 12 weeks than did adolescents receiving enhanced usual care (69.2% vs. 34.6%;  $p = .01$ ; OR= 4.25) and at 24 weeks (82.1% vs. 46.2%;  $p = .006$ ; OR=5.37) (Diamond et al., 2010).

- **Treatment to prevent re-attempts.**

**Emergency Department Brief Intervention with Follow-up Visits** is a program that involves a one-hour discharge information session that addresses suicidal behavior, distress, risk and protective factors, alternatives to suicidal behavior, and referral options, combined with nine follow-up contacts over 18-months (at 1, 2, 4, 7, 11 weeks and 4, 6, 12, 18 months). Follow-up contacts are either conducted by phone or through home visits according to a specific time line for up to 18-months. A randomized controlled trial that enrolled suicide attempters from eight hospital emergency departments in five culturally different sites found that a brief intervention combined with 9 follow-up visits over 18-months was associated with significantly fewer deaths

from suicide relative to a treatment-as-usual group (0.2% versus 2.2%, respectively;  $\chi^2 = 13.83$ ,  $P < 0.001$ ) (Fleischmann et al., 2008).

**Active follow-up contact approaches** such as postcards, letters, and telephone calls, are intended to increase a patient's sense of connectedness with health care providers and decrease isolation. These approaches include expression of care and support and typically invite patients to reconnect with their provider. Contacts are made periodically (e.g., monthly or every few months in the first 12 months post-discharge with some programs continuing contact for 2 or more years). These approaches have been found in a meta-analysis conducted by Inagaki et al. (2015) to reduce reattempts by approximately 17% for up to 12 months post-discharge, however, the long-term effects of these approaches on reattempts has not yet been demonstrated. Also, because the number of trials and associated sample sizes included in this meta-analysis were small, it was not possible to determine the effect of active contact and follow-up approaches on death by suicide. In a randomized controlled trial of post-crisis suicide prevention long-term follow-up contact approach, Motto and Bostrom (2001) found that patients who refused ongoing care but who were randomized to be contacted by letter four times per year had a lower rate of suicide over two years of follow-up than did patients in the control group who received no further contact. Other studies have also shown post-crisis letters and coping cards to be protective against suicide ideation and attempts (Hassanian-Moghaddam, Sarjami, Kolahi, & Carter, 2011; Wang et al., 2016).

**Cognitive Behavior Therapy for Suicide Prevention (CBT-SP)** uses a risk reduction, relapse prevention approach that includes an analysis of proximal risk factors and stressors (e.g., relationship problems, school or work-related difficulties) leading up to and following the suicidal event; safety plan development; skill building; and psychoeducation. *CBT-SP* also has family skill modules focused on family support and communication patterns as well as improving the family's problem solving skills. A randomized controlled trial found of *CBT-SP* found that 10-session outpatient cognitive therapy designed to prevent repeat suicide attempts resulted in a 50% reduction in the likelihood of a suicide reattempt among adults who had been admitted to an emergency department for a suicide attempt relative to treatment as usual (Brown et al., 2005).

- **Postvention** programs such as *StandBy Response Service* are implemented with the goal of providing support to survivors of suicide. *StandBy* provides clients with face-to-face outreach and telephone support through a professional crisis response team. Site coordinators develop customized case management plans, referring clients to other existing community services matched to their needs (Visser, Comans, & Scuffham, 2014). In a study by Visser et al. (2014), *StandBy* clients were significantly less likely to be at high risk for suicidality than a suicide bereaved comparison group who had not had contact with the *StandBy* program (48% and 64% respectively,  $p = 0.005$ ). Additionally, research suggests that active postvention approaches in

which outreach to suicide survivors occurs at the scene of a suicide is associated with intake into treatment sooner, greater attendance at support group meetings, and attendance at more meetings compared to passive postvention (versus passive approaches where survivors self-refer for services) (J. Cerel & Campbell, 2008).

- **Safe messaging following a suicide.** *Media guidelines* for reporting on suicides can help assure that stories on suicide are communicated in a safe and effective way. Reports that are both inclusive of suicide prevention messages, stories of hope and resilience, risk and protective factors, and links to helping resources (e.g., hotline) and that avoid sensationalizing events or reducing suicide to one cause can help reduce the likelihood of suicide contagion. The most compelling evidence supporting the effect of *media guidelines* on reduction in suicides comes from Austria. After a sharp increase in suicides on the Viennese subway, media guidelines were introduced and an interrupted time series design was used to evaluate the national impact of the guidelines on subsequent suicides. Changes in the quality and quantity of media reporting resulted in a reduction of 81 suicides annually (95% confidence interval: -149 to -13;  $t = -2.32$ ,  $df = 54$ ,  $p < 0.024$ ) in the Viennese subway system (Niederkrotenthaler & Sonneck, 2007)

## Sector Involvement

Public health can play an important and unique role in addressing suicide. Public health agencies, which typically place prevention at the forefront of efforts and work to create broad population-level impact, can bring critical leadership and resources to bear on this problem. For example, these agencies can serve as a convener, bringing together partners and stakeholders to plan, prioritize, and coordinate suicide prevention efforts. Public health agencies are also well positioned to collect and disseminate data, implement preventive measures, evaluate programs, and track progress. Although public health can play a leadership role in preventing suicide, the strategies and approaches outlined in this technical package cannot be accomplished by the public health sector alone.

Other sectors vital to implementing this package include, but are not limited to, education, government (local, state, and federal), social services, health services, business/labor, justice, housing, media, and organizations that comprise the civil society sector such as faith-based organizations, youth-serving organizations, foundations, and other non-governmental organizations. Collectively, these sectors can make a difference in preventing suicide by impacting the various contexts and underlying risks that contribute to suicide.

The strategies and approaches described in this technical package are summarized in Appendix A along with the relevant sectors that are well positioned to lead implementation efforts.

[Linda to insert text specific to the strategies and approaches]

Regardless of strategy, action by many sectors will be necessary for the successful implementation of this package. In this regard, all sectors can play an important and influential role in creating safe and protective environments where individuals who are at high risk of suicide can easily access the mental healthcare and services they need.

## Monitoring and Evaluation

Monitoring and evaluation are necessary components of the public health approach to prevention. It is important to have timely and reliable data to monitor the extent of the problem and to evaluate the impact of prevention efforts. Data are necessary for program implementation; planning, implementation, and assessment all rely on accurate measurement of the problem.

Surveillance data helps researchers and practitioners track changes in the burden of suicide. Surveillance systems exist at the federal, state, and local levels. It is important to assess the availability of surveillance data and data systems across these levels to identify and address gaps in the systems. CDC's National Vital Statistics System and the National Violent Death Reporting System (NVDRS) are examples of surveillance systems that provide data on deaths from suicide. NVDRS, for example, is a state-based surveillance system that combines data from death certificates, law enforcement reports, and coroner or medical examiner reports to provide detailed information on the circumstances of violent deaths, including suicide, which can assist communities in guiding prevention approaches (Blair, Fowler, Jack, & Crosby, 2016). The National Electronic Injury Surveillance System-All Injury Program (NEISS-AIP) provides nationally representative data about all types and causes of nonfatal injuries treated in U.S. hospital emergency departments, and can be used to assess national rates of, and trends in, self-harm injuries by cause (e.g., falls, poisoning, etc.), age, race/ethnicity, sex, disposition (where the injured person goes when released from the Emergency Department).

In addition to information on deaths and nonfatal injuries, there are also surveillance systems that provide national, state, and some local estimates of suicidal behavior. The Youth Risk Behavior Surveillance System (YRBSS) collects information from a nationally representative sample of 9-12 grade students and is a key resource in monitoring health-risk behaviors among youth, including whether youth have seriously considered attempting suicide, attempted suicide, made a plan, or required treatment by a doctor or nurse for a suicide attempt that resulted in an injury, poisoning, or overdose (Brener et al., 2013). The YRBSS data are obtained from a national school-based survey conducted by CDC as well as school-based state, territorial, tribal, and large urban school district survey conducted by education and health agencies. The National Survey on Drug Use and Health (NSDUH) is an annual nationwide survey of individuals aged 12 years and older that provides national and state-level estimates of drug use and mental health-related issues, including suicide ideation and suicide attempts.

It is also important at all levels (local, state, and federal) to address gaps in responses, track progress of prevention efforts and evaluate the impact of those efforts, including the impact of this technical package. Evaluation data, produced through program implementation and monitoring, is essential to provide information on what does and does not work to reduce rates of suicide and its associated risk and protective factors. Theories of change and logic models that identify short, intermediate, and long-term outcomes are an important part of program evaluation.

The evidence-base for suicide prevention has advanced greatly over the last few decades. However, additional research is needed to understand the impact of prevention programs on preventing suicide, as opposed to merely examining the effectiveness of programs to impact risk factors associated with suicide. More research is also needed to examine the effectiveness of upstream and community-level strategies to prevent suicide at the population level. Lastly, it will be important for researchers to test the effectiveness of combinations of the strategies and approaches included in this package. Most existing evaluations focus on approaches implemented in isolation. However, there is potential to understand the synergistic effects within a comprehensive prevention approach. Additional research is needed to understand the extent to which combinations of strategies and approaches result in greater reductions in suicide than individual programs, practices, or policies.

## Conclusion

Suicide is a serious public health problem whose rates have been on the rise for more than a decade and whose costs stretch well into the billions of dollars each year. And while suicide is a rare outcome statistically, its human impact has a ripple effect that is far-reaching. Each of us likely interacts with suicide survivors, those with lived experience, and those with thoughts of suicide, on a daily basis—at home, at work, and in our communities. Suicide and suicide attempts are therefore public health issues of societal concern. Fortunately, like many public health problems, suicide is preventable, and fortunately more is being done to prevent suicide than ever before, as evidenced by the work of the National Action Alliance for Suicide Prevention, the release of the first world report on suicide, more timely surveillance data, and critical mention in the President’s FY17 budget, to name just a few examples. Unfortunately and unlike most other public health problems, suicide still struggles against stigma, shame, and secrecy related to help-seeking, mental illness, being a survivor, or someone with lived experience; misplaced fear of asking someone about their risk of suicide (versus the fear and consequence of not asking), and fear of taking up certain strategies known to be effective but perhaps unpopular; misinformation about suicide preventability, and disproportionate funding given the public health burden. Suicide also struggles against the right degree of awareness where too much information, for example by well-meaning reporters and others, may actually do harm.

In an effort to continue pushing the field and society further towards prevention, this technical package includes strategies and approaches that ideally would be used in a comprehensive fashion, in combination—in a multi-level, multi-sectoral way. This technical package includes strategies and approaches targeting upstream prevention, e.g., social emotional learning for children and youth, as well as strategies focused more downstream, e.g., cognitive behavioral treatment to prevent re-attempts. It includes universal, selective, and indicated strategies, or strategies that focus on the whole population regardless of risk to strategies that focus on those groups at highest risk. Importantly, this technical package extends the bounds of the typical prevention strategies to consider approaches at the outer

levels of the social ecology, e.g., policies to stabilize housing and community engagement initiatives. In short, care and attention has been paid to all aspects of suicide prevention.

While the evidence base continues to be built, the collection of programs, policies, and practices laid out here are available for implementation now. And in keeping with good public health practice, the intent is that monitoring and evaluation will play a key role in that implementation. Moreover, as new evidence becomes available, this technical package can be refined to reflect the current state of the science.

In closing, and in keeping with a message of resilience as spoken by those with lived experience, ‘hope, help, and healing is possible.’

## Appendix A: Summary of Strategies and Approaches to Prevent Suicide

Strategy	Approach/Program, Practice or Policy	Best Available Evidence			Lead Sectors <sup>1</sup>
		Suicide	Suicide Attempts or Ideation	Other Risk/Protective Factors for Suicide	
Strengthen economic supports	Strengthen household financial security				
	Unemployment benefit programs	✓			Government (local, state, Federal)
	Housing stabilization policies				
	The National Neighborhood Stabilization Program			✓	Government (local, state, Federal)
Strengthen access to mental health care	Coverage of mental health conditions in health insurance policies				
	Mental Health Parity Laws	✓		✓	Government (state, Federal)  Health care
Establish protective environments	Reducing access to lethal means among persons at-risk				
	Intervening at hot spots	✓			Government (local, state, Federal)
	Safe storage practices		✓	✓	Public Health
	Organizational policies and culture				
	Together for Life	✓			Business/Labor

		Best Available Evidence			
	<i>US Air Force Suicide Prevention Program</i>	✓		✓	Government (local, state, Federal)
	Community-based policies to reduce excessive alcohol use				
	<i>Alcohol outlet density</i>	✓		✓	Government (local, state, Federal)
Promote connectedness to protect against suicide	Peer norm approaches				
	<i>Sources of Strength</i>			✓	Public Health Social Services
	Community-engagement activities				
	<i>Greening vacant urban spaces</i>			✓	Public Health
Teach coping and problem- solving skills	Social emotional learning				
	<i>Youth Aware of Mental Health Program</i>		✓		Public Health
	<i>Signs of Suicide</i>		✓	✓	Education
	<i>Good Behavior Game</i>		✓	✓	
	Parenting skill and family relationship approaches				
	<i>The Incredible Years</i>			✓	Public Health
				Education	

		Best Available Evidence			
	<i>Strengthening Families 10-14</i>			✓	
Identify and support people at-risk	Gatekeeper training				
	<i>Mental Health First Aid</i>			✓	Public Health Healthcare Social Services
	Screening combined with care management				
	<i>Henry Ford Perfect Depression Care (Pre-cursor to Zero Suicide)</i>	✓		✓	Healthcare
	Crisis Intervention				
	<i>National Suicide Prevention Lifeline</i>		✓	✓	Public Health Social Services
	<i>Applied Suicide Intervention Skills Training</i>		✓	✓	
Treatment for people at risk of suicide					
<i>Improving Mood – Promoting Access to Collaborative Treatment (IMPACT)</i>		✓	✓	Healthcare Social Services	
<i>Collaborative Assessment and Management of Suicidality (CAMS)</i>		✓	✓		

		Best Available Evidence			
Intervene to lessen harms and prevent future risk	<i>Dialectical Behavioral Therapy</i>		✓	✓	
	<i>Attachment-Based Family Therapy</i>		✓		
	Treatment to prevent re-attempts				
	<i>ED Brief Intervention with Follow-up Visits</i>	✓			Healthcare
	<i>Active follow-up contact approaches</i>	✓	✓		
	<i>CBT for Suicide Prevention</i>				
	Postvention				
	<i>StandBy Response Service</i>		✓		Healthcare
	Safe messaging following a suicide				
	<i>Media Guidelines</i>	✓			Public Health

<sup>1</sup>This column refers to the lead sectors well positioned to bring leadership and resources to implementation efforts. For each strategy, there are many other sectors such as non-governmental organizations that are instrumental to prevention planning and implementing the specific programmatic activities.

**Comment [A]:** One idea. Should we add relationships? Keep the levels the same as the SEM or is this ok?

## Overview

This technical package represents a select group of strategies based on the best available evidence to help communities and states sharpen their focus on prevention activities with the greatest potential to prevent suicide. These strategies include strengthening economic supports; strengthening access to mental health care; creating protective environments; promoting connectedness to protect against suicide; teaching coping and problem-solving skills; identifying and supporting people at-risk; and intervening to lessen harms and prevent future risk. The strategies represented in this package include those with a focus on preventing suicide from happening in the first place as well as approaches to lessen the immediate and long-term harms of suicidal behavior for individuals, families, communities, and society. The strategies in the technical package support the goals and objectives of the National Strategy for Suicide Prevention and the National Action Alliance for Suicide Prevention's priority to strengthen community-based prevention. Commitment, cooperation, and leadership from numerous sectors, including public health, education, justice, health care, social services, business/labor, and government can bring about the successful implementation of this package.

### What is a Technical Package?

A technical package is a compilation of a core set of strategies to achieve and sustain substantial reductions in a specific risk factor or outcome (Frieden, 2014). Technical packages help communities and states prioritize prevention activities based on the best available evidence. This technical package has three components. The first component is the **strategy** or the preventive direction or actions to achieve the goal of preventing suicide. The second component is the **approach**. The approach includes the specific ways to advance the strategy. This can be accomplished through *programs, policies, and practices*. The approaches included come primarily from studies based in the United States. The **evidence** for each of the approaches in preventing suicide or its associated risk factors is included as the third component. This package is intended as a resource to guide and inform prevention decision-making in communities and states.

### Preventing Suicide is a Priority

Suicide, as defined by the Centers for Disease Control and Prevention (CDC), is part of a broader class of behavior called *self-directed violence*. Self-directed violence refers to behavior directed at oneself that deliberately results in injury or the *potential* for injury (Crosby, Ortega, & Melanson, 2011). Self-directed violence may be *suicidal* or *non-suicidal* in nature. For the purposes of this document, we refer only to behavior where suicide is intended:

- **Suicide** is a death caused by self-directed injurious behavior with any intent to die as a result of the behavior.

- **Suicide attempt** is defined as a *non-fatal* self-directed and potentially injurious behavior with any intent to die as a result of the behavior. A suicide attempt may or may not result in injury.

**Suicide is highly prevalent.** Suicide presents a major challenge to public health in the United States and worldwide. It contributes to premature death, morbidity, lost productivity, and health care costs (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014). In 2014 (the most recent year of available death data), suicide was responsible for 42,773 deaths in the U.S., which is approximately one suicide every 12 minutes (Centers for Disease Control and Prevention, 2016d). In 2014, suicide ranked as the 10th leading cause of death and has been among the top 12 leading causes of death since 1975 in the U.S (Centers for Disease Control and Prevention, 2016d). Overall suicide rates have increased 24% from 1999 to 2014 (Curtin, Warner, & Hedegaard, 2016). Suicide is a problem throughout the life span; it is the second leading cause of death among those aged 10–19 years, also second among persons in their 20s and 30s; it is the fourth leading cause among persons in their 40s and seventh among persons in their 50s (Centers for Disease Control and Prevention, 2016d).

Suicides reflect only a portion of the problem (Crosby, Han, Ortega, Parks, & Gfroerer, 2011). Substantially more people are hospitalized as a result of nonfatal suicidal behavior (i.e. suicide attempts) than are fatally injured, and an even greater number are either treated in ambulatory settings (e.g., emergency departments) or not treated at all (Crosby, Han, et al., 2011). For example, during 2014, among adults aged 18 years and older, for every one suicide there were 9 adults treated in hospital emergency departments for self-harm injuries, 27 who reported making a suicide attempt, and over 227 who reported seriously considering suicide (i.e. ideation) (Ferdon et al., In press).

**Suicide is associated with several risk and protective factors.** Suicide, like other human behaviors, is complex with no single determining cause. Instead, suicide occurs in response to multiple biological, psychological, interpersonal, environmental and societal influences that interact with one another, often over time. The social-ecological model-- encompassing multiple levels of focus from the individual, relationship, community, and societal-- is a useful framework for viewing and understanding suicide risk factors identified in the literature (Dahlberg & Krug, 2002). Risk and protective factors for suicide exist at each level. For example, risk factors include:

- **Individual level:** History of depression and other mental illnesses, alcohol and drug abuse, previous suicide attempt, violence victimization, genetic and biological determinants, hopelessness
- **Relationship level:** High conflict or violent relationships, sense of isolation and lack of social support, family/loved one's history of suicide, financial and work stress
- **Community level:** Inadequate community connectedness, barriers to health care (e.g., lack of access to providers and medications)

- **Societal level:** Availability of lethal means of suicide, unsafe media portrayals of suicide, stigma associated with help-seeking and mental illness (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014).

It is important to recognize that the vast majority of individuals who are depressed or who have other risk factors noted, do *not* die by suicide. Furthermore, the relevance of each risk factor can vary by age, race, gender, sexual orientation, residential geography, and socio-cultural and economic status (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014).

Protective factors, or those influences that guard *against* the risk for suicide, can also be found across the different levels of the social-ecological model. Protective factors identified in the literature include: effective coping and problem solving skills, moral objections to suicide, strong and supportive relationships with partners, friends, and family; connectedness to school, community and other social institutions; availability of quality and ongoing physical and mental health care, and reduced access to lethal means (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014). These protective factors can either counter a specific risk factor or guard against a number of risks associated with suicide.

**Suicide is connected to other forms of violence.** Suicide and other forms of violence often share some of the same root causes (Butchart, Phinney, Check, & Villaveces, 2004; Klevens, Simon, & Chen, 2012). For example, in neighborhoods where there is low social cohesion, or where residents don't support and trust each other, people are at higher risk for suicide (Desai, Dausey, & Rosenheck, 2005) as well as perpetration of child maltreatment (Coulton, Crampton, Irwin, Spilsbury, & Korbin, 2007; Freisthler, Merritt, & LaScala, 2006), teen dating violence (Capaldi, Knoble, Shortt, & Kim, 2012), intimate partner violence (Pinchevsky & Wright, 2012), and youth violence (Sampson, Morenoff, & Gannon-Rowley, 2002). Additionally, a lack of economic opportunities and unemployment are associated with suicide (Luo, Florence, Quispe-Agnoli, Ouyang, & Crosby, 2011; Reeves et al., 2012), as well as perpetration of child maltreatment (D. Runyan, Wattam, Ikeda, Hassan, & Ramiro, 2002), intimate partner violence (Heise & Garcia-Moreno, 2002; Pinchevsky & Wright, 2012), sexual violence (Centers for Disease Control and Prevention, 2016c) and youth violence (Wilson, 2011). Other shared risk factors for suicide and violence occur at the individual level and include substance abuse, mental health problems, witnessing violence, and a lack of problem-solving skills (Centers for Disease Control and Prevention, 2016a, 2016c, 2016e; U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012).

Just as risk factors may be shared across suicide and violence, so too may protective factors overlap. For example, connectedness increases individual's and communities' resilience to suicide and other forms of violence, including connectedness to one's community (Basile, Hamburger, Swahn, & Choi, 2013; Borowsky, Hogan, & Ireland, 1997; Centers for Disease Control and Prevention, 2016b; Coulton et al.,

2007; Kleiman, Riskind, Schaefer, & Weingarden, 2012; Pinchevsky & Wright, 2012; Widome, Sieving, Harpin, & Hearst, 2008), school (Basile, Espelage, Rivers, McMahon, & Simon, 2009; Capaldi et al., 2012; Carter, McGee, Taylor, & Williams, 2007; DeGue et al., 2013; Hong, Kral, Espelage, & Allen-Meares, 2012; Losel & Farrington, 2012), family (Capaldi et al., 2012; Centers for Disease Control and Prevention, 2016a; Elgar, Craig, Boyce, Morgan, & Vella-Zarb, 2009; Maimon, Browning, & Brooks-Gunn, 2010; Resnick, Ireland, & Borowsky, 2004), caring adults (Capaldi et al., 2012; Losel & Farrington, 2012; Maimon et al., 2010), and pro-social peers (Capaldi et al., 2012; Losel & Farrington, 2012).

**The health and economic consequences of suicide are substantial.** Suicide and suicide attempts have far-reaching consequences for individuals, families, and communities (Dunne, McIntosh, & Dunne-Maxim, 1987; Mishara, 1995; National Action Alliance for Suicide Prevention: Suicide Attempt Survivors Task Force, 2014; National Action Alliance for Suicide Prevention: Survivors of Suicide Loss Task Force, 2015). By one conservative estimate, for every death by suicide six people are directly impacted (i.e. survivors). Based on this figure it is estimated that there are over 13 million survivors in the U.S. and unfortunately, survivorship itself is a risk factor for suicide (Crosby & Sacks, 2002). Research indicates that the health consequences of violence, including suicide, are also much more extensive than injury and death. Suicide attempt survivors (i.e. those with lived experience) may suffer long-term health and mental health consequences ranging from anger, guilt, and physical impairment, depending on the means and severity of the attempt (Chapman & Dixon-Gordon, 2007). Similarly, survivors of a loved one's suicide may experience ongoing pain and suffering including complicated grief (Mitchell, Kim, Prigerson, & Mortimer-Stephens, 2004), stigma, depression, anxiety, post-traumatic stress disorder, and increased risk of suicidal ideation and suicide (Julie Cerel, McIntosh, Neimeyer, Maple, & Marshall, 2014; Sudak, Maxim, & Carpenter, 2008).

The economic toll of suicide is immense as well. The total lifetime costs associated with nonfatal injuries and deaths caused by self-directed violence in 2013 were approximately \$93.5 billion after adjusting for under-reporting of suicide (Shepard, Gurewich, Lwin, Reed, & Silverman, 2016). The overwhelming burden of these costs results from lost productivity over the life course, with the average cost per suicide being over \$1.3 million (Shepard et al., 2016).

**Suicide can be prevented.** Despite the myths surrounding suicide, like most public health problems, suicide is preventable (U.S. Public Health Service, 1999). And while progress will continue to be made into the future, evidence for numerous programs, practices, and policies currently exists, and many programs are ready to be implemented now. Just as suicide is not caused by a single factor, research suggests that suicide will not be prevented by any single intervention taking place in any single setting (Silverman & Maris, 1995; U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012). Rather, suicide prevention is best achieved by a focus across the individual-, relationship-, family-, community, and societal-levels and across all sectors, private and public (e.g.,

business, public health, physical and behavioral healthcare, justice, education, labor) (National Action Alliance for Suicide Prevention, 2014; World Health Organization, 2014).

### **Assessing the Evidence**

This technical package includes programs, practices, and policies with evidence of impact on suicide or risk or protective factors for suicide. To be considered for inclusion in the technical package, the program, practice, or policy selected had to meet at least one of these criteria: a) meta-analyses or systematic reviews showing impact on suicide; b) evidence from at least one rigorous (e.g., randomized controlled trial [RCT] or quasi-experimental design) evaluation study that found significant preventive effects on suicide; c) meta-analyses or systematic reviews showing impact on risk or protective factors for suicide, or d) evidence from at least one rigorous (e.g., RCT or quasi-experimental design) evaluation study that found significant impacts on risk or protective factors for suicide. Finally, consideration was also given to the likelihood of achieving beneficial effects on multiple forms of violence; no evidence of harmful effects on specific outcomes or with particular subgroups; and feasibility of implementation in a U.S. context if the program, policy, or practice has been evaluated in another country.

Within this technical package, some approaches do not yet have research evidence demonstrating impact on rates of suicide but instead are supported by evidence indicating impacts on risk or protective factors for suicide (e.g., help-seeking, stigma reduction, depression, connectedness). In terms of the strength of the evidence, programs that have demonstrated effects on suicidal behavior (e.g., reductions in deaths, attempts) provide a higher-level of evidence, but the evidence base is not that strong in all areas. For instance, there has been less evaluation of community engagement and family programs on suicidal behavior. Thus, approaches in this package that have effects on risk or protective factors reflect the developmental nature of the evidence base and the use of the best available evidence at a given time.

It is also important to note that there is often significant heterogeneity among the programs, policies, or practices that fall within one approach or strategy area in terms of the nature and quality of the available evidence. Not all programs, policies, or practices that utilize the same approach (e.g., gatekeeper training) are equally effective, and even those that are effective may not work across all populations. Tailoring programs and more evaluation may be necessary to address different population groups. The examples provided are not intended to be a comprehensive list of evidence-based programs, policies, or practices for each approach, but rather illustrate models that have been shown to impact suicide or have beneficial effects on risk or protective factors for suicide. In practice, the effectiveness of the programs, policies and practices identified in this package will be strongly dependent on the quality of their implementation and the communities in which they are implemented. Implementation guidance to assist practitioners, organizations and communities will be developed separately.

### Context and Cross-Cutting Themes

The strategies and approaches that have been included in this technical package represent different levels of the social ecology, with efforts intended to impact the community and societal levels, as well individual and relationship levels. The strategies and approaches are intended to work in combination and reinforce each other to prevent suicide (see box below). The strategies are arranged in order such that those strategies hypothesized to have the greatest potential for broad public health impact on suicide are included first, followed by those that might impact more select populations (e.g., persons who have already made a suicide attempt).

**Comment [A]:** Can we just call this Promote Connectedness so it's more consistent with other strategy titles? Seems like 'to protect against suicide' is implied in all of the strategies.

Preventing Suicide	
Strategy	Approach
Strengthen economic supports	<ul style="list-style-type: none"><li>Strengthen household financial security</li><li>Housing stabilization policies</li></ul>
Strengthen access to mental health care	<ul style="list-style-type: none"><li>Coverage of mental health conditions in health insurance policies</li></ul>
Create protective environments	<ul style="list-style-type: none"><li>Reducing access to lethal means among persons at-risk of suicide</li><li>Organizational policies and culture</li><li>Community-based policies to reduce excessive alcohol use</li></ul>
Promote connectedness to protect against suicide	<ul style="list-style-type: none"><li>Peer norm approaches</li><li>Community engagement activities</li></ul>
Teach coping and problem-solving skills	<ul style="list-style-type: none"><li>Social-emotional learning</li><li>Parenting skill and family relationship approaches</li></ul>
Identify and support people at risk	<ul style="list-style-type: none"><li>Gatekeeper training</li><li>Screening combined with care management</li><li>Crisis intervention</li></ul>
Intervene to lessen harms and prevent future risk	<ul style="list-style-type: none"><li>Treatment for people at-risk of suicide</li><li>Treatment to prevent re-attempts</li><li>Postvention</li><li>Safe messaging following a suicide</li></ul>

The example programs, policies, and practices have been implemented within particular contexts. The social and cultural context of communities is critically important to take into account when selecting strategies and approaches. Practitioners in the field may be in the best position to assess the needs and strengths of their communities and work with community members to make decisions about the combination of approaches included here that are best suited to their context.

Suicide ideation, attempts, morbidity and mortality vary by gender, race/ethnicity, age, occupation, and other important population characteristics. Barriers to disclosure, help seeking, timely access to quality care, and ongoing support are profoundly complex and may also vary by population and community characteristics. Ideally, the availability of multiple approaches tailored to the economic, cultural, and environmental context of individuals and communities are desirable as they may increase the likelihood of removing barriers to supportive and effective care and provide opportunities to develop individual and community resilience. These culturally appropriate approaches can then be included in comprehensive strategies to maximize the public health impact on reducing suicide-related morbidity and mortality among individuals and within communities.

This package includes strategies where public health agencies are well positioned to bring leadership and resources to implementation efforts. It also includes strategies where public health can serve as an important collaborator (e.g., strategies addressing community and societal level risks), but where leadership and commitment from other sectors such as business/labor or health care is critical to implement a particular policy or program (e.g., workplace policies; screening combined with care management). The role of various sectors in the implementation of a strategy or approach in preventing suicide is described further in the section on *Sector Involvement*.

In the sections that follow, the strategies and approaches with the best available evidence for preventing suicide are described.

## Strengthen Economic Supports

### Rationale

Studies from the U.S. examining historical trends indicate that suicide rates increase during economic recessions marked by high unemployment rates, job losses, and economic instability and decrease during economic expansions and periods marked by low unemployment rates, particularly for working-age individuals 25 to 64 years old (Luo et al., 2011; Fowler et al., 2015). Economic and financial strain, such as job loss, long periods of unemployment, reduced income, difficulty covering medical, food, and housing expenses, and even the anticipation of such financial stress, increase an individual's risk for suicide; buffering these risks can therefore, potentially protect against suicide (Stack & Wasserman, 2007). For example, strengthening economic support systems can help people pay stay in their homes or obtain affordable housing while also paying for necessities such as food and medical care, job training, child care, among other expenses required for daily living. In providing this support, stress and anxiety and the potential for a crisis situation may be reduced, thereby preventing suicide.

### Approaches

Economic supports for individuals and families can be strengthened by targeting household financial security and ensuring stability in housing during periods of economic stress.

- **Strengthening household financial security** can **reduce** the risk of suicide by providing individuals with the financial means to cover basic expenses and lessen the stress and hardship associated with a job loss or other unanticipated financial problems. The provision of unemployment benefits, livable wages, Temporary Assistance to Needy Families (TANF), medical benefits, and retirement and disability insurance to help cover the cost of necessities or to offset costs in the event of disability are examples of ways to strengthen household financial security.
- **Housing stabilization policies** aim to keep people in their homes and provide housing options for those in need during times of financial insecurity. This may occur through programs that provide affordable housing such as through government subsidies or through other options available to potential homebuyers such as loan modification programs, move-out planning, or financial counseling services that help minimize the risk or impact of foreclosures and eviction.

### Potential Outcomes

- Reduced suicide rates
- Lower foreclosure rates
- Lower eviction rates
- Reduced emotional distress

**Comment [A]:** Linda, do you think we should say can theoretically reduce the risk...same question for housing.

## Evidence

There is evidence suggesting that strengthening household financial security and stabilizing housing can reduce suicide risk.

- **Strengthen household financial security.** An examination of variations in U.S. *unemployment benefit programs* across states demonstrated that the impact of unemployment on suicide was offset in those states that provided greater than average unemployment benefits (Cylus, Glymour, & Avendano, 2014). Another U.S. study examining the link between unemployment and suicide risk using monthly suicide data, length of unemployment, and job losses found that the duration of unemployment, as opposed to just the loss of job, predicted suicide risk (Classen & Dunn, 2012). Together, these results suggest that not only should state unemployment benefit programs be generous in their financial allocations, but also in their duration. Other measures to strengthen household financial security (e.g., transfer payments related to retirement and disability insurance, unemployment insurance compensation, medical benefits, and other forms of family assistance) have also shown an impact on suicide. A study by Flavin and Radcliff (2009) examined the impact of states' per capita spending on transfer payments, medical benefits, and family assistance and total state spending on suicide rates between 1990-2000, controlling for a number of suicide risk factors (e.g., residential mobility, divorce rate, unemployment rate) at the state level. As per capita spending on total transfer payments, medical benefits, and family assistance increased there was an associated decrease in state suicide rates. Moreover, it wasn't spending in general that was associated with the reduction but spending on these types of assistance. In terms of lives saved, Flavin & Radcliff calculated the cost of reducing a state's suicide rate by a full point for the years studied. At the national level, an estimated 3,000 fewer suicides would occur per year nationwide if every state increased their per capita spending on these types of assistance by \$45 per year (Flavin & Radcliff, 2009).
- **Housing stabilization policies.** The *National Neighborhood Stabilization Program* was designed to help neighborhoods suffering from high rates of foreclosure and abandonment by slowing the deterioration of the neighborhoods and providing affordable housing options for low, moderate, and middle-income homebuyers. This program also offers financial assistance to eligible individuals for the purchase of a new home. Although this program has not been rigorously evaluated for its impact on suicide outcomes, it addresses foreclosure and eviction, which are risk factors for suicide. A longitudinal analysis of annual data on suicides and foreclosures demonstrated that as the proportion of foreclosed properties increased in U.S. states, so did the state suicide rate, particularly among working-aged adults (Houle & Light, 2014). Another study of data from 16 U.S. states participating in the National Violent Death Reporting System found that suicides precipitated by home foreclosures and evictions increased more than 100% from

2005 (before the housing crisis began) to 2010 (after it had peaked; Fowler, Gladden, Vagi, Barnes, and Frazier (2015)). Most of these suicides occurred prior to the actual loss of the decedent's home. These findings suggest that integrating suicide prevention resources, messaging, and referrals into financial, foreclosure, and move-out planning and counseling services may help to prevent suicide.

## Strengthen Access to Mental Health Care

### Rationale

While most people with mental health problems do not attempt or die by suicide (Olfson, Gerhard, Huang, Crystal, & Stroup, 2015; Owens, 2002), and risk conferred by mental illnesses differ (Arsenault-Lapierre, Kim, & Turecki, 2004; E. C. Harris & Barraclough, 1997; Tyrer, Reed, & Crawford, 2015), previous research indicates that mental illness is an important risk factor for suicide (E. C. Harris & Barraclough, 1998; World Health Organization, 2014). Studies suggest that up to 90% of people who die by suicide may have had a mental illness at the time of their deaths (Arsenault-Lapierre et al., 2004; Cavanagh, Carson, Sharpe, & Lawrie, 2003; Isometsa, 2001). State-level suicide rates have also been found to be correlated with general mental health measures such as depression (Lang, 2013; Mark, Shern, Bagalman, & Cao, 2007). Findings from the National Comorbidity Survey indicate that relatively few people in the U.S. with mental health disorders receive treatment for those conditions (Kessler et al., 2005). Lack of access to mental health care is one of the contributing factors related to the underuse of mental health services (Cunningham, 2009). Identifying ways to improve access to timely, affordable, and quality mental health care for people in need is a critical component to suicide prevention (World Health Organization, 2014). Apart from the treatment benefits, it can also serve to normalize help-seeking behavior and increase the use of such services.

### Approaches

One approach to strengthening access to mental health care is through the provision of mental health coverage in health insurance policies.

- **Coverage of mental health conditions in health insurance policies.** Federal and state laws include provisions for equal coverage of mental health services in health insurance plans that is on par with coverage for other health concerns (i.e., mental health parity). Benefits and services covered include such things as the number of visits, co-pays, deductibles, inpatient/outpatient services, prescription drugs, and hospitalizations. If a state has a stronger mental health parity law than the federal parity law, then insurance plans regulated by the state must follow the state parity law. Federal parity replaces the state law only in cases where the state law prevents the application of the federal parity law (e.g., includes coverage for some mental health conditions but not others). Equal coverage does not necessarily imply good coverage as health insurance plans vary in the extent to which benefits and services are offered to address various health conditions. Rather it helps to ensure that mental health services are covered on par with other health concerns.

### Potential Outcomes

- Increased utilization of mental health services

- Decreased symptoms of mental illnesses
- Decreased rates of suicide attempts
- Decreased rates of suicide

## Evidence

There is evidence suggesting that coverage of mental health conditions in health insurance policies can reduce risk factors associated with suicide and may directly impact suicide rates.

- **Coverage of mental health conditions in health insurance policies.** The National Survey of Drug Use and Health is a nationally representative survey of the U.S. population that provides data on substance use, mental health conditions, and services utilization. Using data from this survey, K. M. Harris, Carpenter, and Bao (2006) found that 12 months after states enacted *mental health parity laws*, self-reported use of mental healthcare services significantly increased. Moreover, subsequent research by Lang (2013) examined state mental health laws and suicide rates between 1990 and 2004 and found that mental health parity laws, specifically, were associated with an approximate 5% reduction in suicide rates. This reduction, in the 29 states with parity laws, equated to the prevention of 592 suicides per year and a cost savings of \$1.3-3.1 million per suicide prevented (Lang, 2013).

## Create Protective Environments

### Rationale

**Comment [A]:** Not sure if the additions I made to the rationale are too duplicative of info below. If so, go ahead and delete.

Prevention efforts that focus not only on individual behavior change (e.g., help-seeking, treatment interventions) but on changes to the environment can increase the likelihood of positive behavioral and health outcomes (Haddon, 1980). Creating environments that address risk and protective factors where individuals live, work, and play, can help prevent suicide (Dahlberg & Krug, 2002; U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012). For example, rates of suicide and suicide attempts are elevated in certain occupational groups (Han et al., 2016; McIntosh et al., 2016), therefore, changes to the organizational culture in these occupations, by way of implementation of supportive policies or even physical modifications to the workplace environment, can demonstrate that good health and mental health are valued and that stigma and other risk factors for suicide, are not (K. L. Knox et al., 2010; National Action Alliance for Suicide Prevention Workplace Task Force, 2015). Similarly, changing the availability of and access to common suicide risk factors in the environment such as bridges, alcohol, medications, or firearms, can reduce suicide rates, particularly in times of crisis (Beautrais, Gibb, Fergusson, Horwood, & Larkin, 2009; Crosby, Espitia-Hardeman, Ortega, & Lozano, 2013; Kaplan et al., 2013; Miller, Warren, Hemenway, & Azrael, 2015; C. W. Runyan et al., 2016).

### Approaches

The current evidence suggests three promising approaches for creating environments that protect against suicide.

- **Reducing access to lethal means among persons at-risk of suicide.** Means of suicide such as firearms, hanging/suffocation, or jumping from heights provide little opportunity for rescue and, as such, have high case fatality rates (e.g., about 85% of people who use a firearm in a suicide attempt will die from the injury). Research also indicates that 1) the interval between thinking about and attempting suicide can be as short as 5 or 10 minutes (Deisenhammer et al., 2009; Simon et al., 2001) and 2) that people tend *not* to substitute a different method when a highly lethal method is unavailable or difficult to access (Hawton, 2007; Yip et al., 2012). Therefore, increasing the time interval between the thought and the suicide attempt, for example, by making it more difficult to access lethal means, can be lifesaving. The following are examples of approaches reducing access to lethal means for persons at-risk of suicide:
  - *Intervening at Suicide Hotspots.* Suicide hotspots, or places where suicides may take place relatively easily, include tall structures (e.g., bridges and cliffs), railway tracks, and isolated locations such as parks. Efforts to prevent suicide at these locations include

erecting barriers to prevent jumping and installing signs and telephones to encourage individuals who are considering suicide, to seek help (Cox et al., 2013).

- *Safe Storage Practices.* Safe storage of medications, firearms, and other household products can reduce the risk for suicide by separating individuals who may be vulnerable and/or impulsive from easy access to lethal means. Such practices may include education and counseling around storing firearms--locked in a secure place (e.g., in a gun safe or lock box), unloaded and separate from the ammunition--and keeping medicines in a locked cabinet or other secure location away from people who may be at risk or who have made prior attempts (Rowhani-Rahbar, Simonetti, & Rivara, 2016; C. W. Runyan et al., 2016).
- **Organizational policies and culture** that promote protective environments may be implemented in places of employment. Such policies and cultural values may promote prosocial behavior (e.g., asking for help), skill building, changing social norms, referral and access to helping services (e.g. mental health, substance abuse treatment, financial counseling), and encourage leadership support from the top down. Such policies and cultural shifts can positively impact organizational climate and morale and help prevent suicide and its related risk factors (e.g. depression, social isolation) (National Action Alliance for Suicide Prevention Workplace Task Force, 2015).
- **Community-based policies to reduce excessive alcohol use.** Research studies in the United States have found that greater alcohol availability is positively associated with alcohol-involved suicides (Escobedo & Ortiz, 2002; Giesbrecht et al., 2015). Policies to reduce excessive alcohol use broadly include zoning to limit alcohol outlet locations and density, taxes on alcohol, and bans on the sale of alcohol for individuals under the legal drinking age. These policies are important because acute alcohol use has been found to be associated with more than one-third of suicides and approximately 40% of suicide attempts (Cherpitel, Borges, & Wilcox, 2004).

### Potential Outcomes

- Increase in safe storage of means
- Reduction in suicide attempts
- Reduction in suicide deaths
- Increase in help-seeking
- Reduction in alcohol-related suicide deaths

### Evidence

The evidence for the effectiveness of means restriction and other ways to establish protective environments is some of the strongest in the field (Zalsman et al., 2016), as described below.

- **Reducing access to lethal means among persons at-risk of suicide.** A meta-analysis examining the impact of *suicide hotspot interventions* implemented in combination or in isolation, both in the U.S. and abroad, found associated reduced rates of suicide (Cox et al., 2013; Pirkis et al., 2015). For example, after erecting a barrier on the Jacques-Cartier bridge in Canada, the suicide rate from jumping from the bridge decreased from about 10 suicide deaths per year to about 3 deaths per year (Perron, Burrows, Fournier, Perron, & Ouellet, 2013). Moreover, the reduction in suicides by jumping was sustained even when all bridges and nearby jumping sites were considered, suggesting little to no displacement of suicides to other jumping sites (Perron et al., 2013). Further evidence for the effectiveness of bridge barriers was demonstrated by a study examining the impact of the *removal* of safety barriers from the Grafton Bridge in Auckland, New Zealand. After removal of the barrier, sadly, both the number and rate of suicide increased fivefold (Beautrais, 2001; Beautrais et al., 2009).

Another form of means reduction involves implementation of *safe storage practices*. In a case-control study of firearm-related events identified from 37 counties in Washington, Oregon, and Missouri, and from 5 trauma centers, Grossman et al. (2005) found that storing firearms unloaded, separate from ammunition, in a locked place and/or secured with a safety device was protective of suicide attempts among adolescents. Further, a recent systematic review of clinic and community-based education and counseling interventions suggested that the provision of safety devices significantly increased safe firearm storage practices compared to counseling alone or compared to the provision of economic incentives to acquire safety devices on one's own (Rowhani-Rahbar et al., 2016).

Another program, *The Emergency Department Counseling on Access to Lethal Means (ED CALM)*, trained psychiatric emergency clinicians in a large children's hospital to provide lethal means counseling and safe storage boxes to parents of patients under age 18 receiving care for suicidal behavior. In a pre-post quality improvement project, Runyan et. al (2016) found that at post-test 76% (of the 55% of parents followed up, n=114) reported that all medications in the home were locked up as compared to fewer than 10% at the time of the initial emergency department visit. Among parents who indicated the presence of guns in the home at pre-test (i.e. 67%), all (100%) reported guns were currently locked up at post-test (C. W. Runyan et al., 2016).

- **Organizational policies and culture.** *Together for Life* is a workplace program of the Montreal Police Force implemented to address suicide among officers. Policy and program components were designed to foster an organizational culture that promoted mutual support and solidarity among all members of the Force. The program included training of supervisors, managers and all units to improve competencies in identifying suicidal risk and to improve use and awareness of existing resources. The program also included an education campaign to improve awareness and help-seeking (Mishara & Martin, 2012). Police suicides were tracked over 12 years and

compared to rates in the control city of Quebec. The suicide rate in the intervention group decreased significantly by 78.9% to a rate of 6.42 suicides per 100,000 population per year compared to an 11% increase in the control city (rate: 29.0 per 100,000) (Mishara & Martin, 2012).

Another example of this approach is the *United States Air Force Suicide Prevention Program (AFSPP)*. AFSPP included 11 policy and education initiatives and was designed to change the culture of the Air Force surrounding suicide. The program uses leaders as role models and agents of change, establishes expectations for behavior related to awareness of suicide risk, develops population skills and knowledge (i.e., education and training), and investigates every suicide (i.e., outcomes measurement). The program represents a fundamental shift from viewing suicide and mental illness solely as medical problem and instead sees them as larger service-wide problems impacting the whole community (K. L. Knox, Litts, Talcott, Feig, & Caine, 2003). Using a time-series design to examine the impact of the AFSPP program on various violence-related outcomes, researchers found that the program was associated with a 33% relative risk reduction in suicide (K. L. Knox et al., 2003). The program was also associated with relative risk reductions in related outcomes including moderate and severe family violence (30% and 54%, respectively), homicide (51%), and accidental death (18%) (K. L. Knox et al., 2003). A longitudinal assessment of the program over the period 1981 to 2008 (16 years before the 1997 launch of the program and 11 years post-launch) found significantly lower rates of suicide after the program was launched than before (K. L. Knox et al., 2010). These effects were sustained over time, except in 2004, which the authors found was associated with less rigorous implementation in that year than in the other years (K. L. Knox et al., 2010).

- **Community-based policies to reduce excessive alcohol use.** While multiple policies to limit alcohol use exist, several studies on alcohol outlet *density*, specifically, suggest that measures to reduce alcohol outlet density can potentially reduce alcohol-involved suicides. Additionally, a longitudinal analysis of alcohol outlet density, suicide mortality, and hospitalizations for suicide attempts over 6 years in 581 California zip codes indicated that the density of bars, specifically, is related to suicide and suicide attempts, particularly in rural areas (Johnson, Gruenewald, & Remer, 2009).

## Promote Connectedness to Protect Against Suicide

### Rationale

Sociologist, Emile Durkheim theorized in 1897 that weak social bonds, i.e. lack of connectedness, are among the chief causes for suicidality (Durkheim, 1897/1951). *Connectedness* is the degree to which an individual or group of individuals are socially close, interrelated, or share resources with others (Centers for Disease Control and Prevention, 2009). Social connections can be formed within and between multiple levels of the social ecology (Dahlberg & Krug, 2002), for instance between individuals (e.g. peers, neighbors, co-workers), families, schools, neighborhoods, workplace, faith communities, cultural groups, and society as a whole. Related to connectedness, *social capital* refers to a sense of trust in one's community and neighborhood, social integration, and also the availability and participation in social organizations (Beyer, Layde, Hamberger, & Laud, 2015; Muennig, Cohen, Palmer, & Zhu, 2013). Many ecological cross-sectional and longitudinal studies have examined the impact of aspects of social capital on depression symptoms, depressive disorder, mental health more generally, and suicide. While the evidence is still being built the pattern is towards an inverse association between social capital measured by social trust, community/ neighborhood engagement, and improved mental health. Connectedness and social capital together can serve to protect against suicidal behaviors by decreasing isolation, encouraging adaptive coping behaviors, increasing belongingness, personal value and worth all of which helps individuals to build resilience in the face of adversity. Connectedness can also provide individuals with better access to formal supports and resources, mobilize communities to meet the needs of its members and provide collective primary prevention activities to the community as a whole (Centers for Disease Control and Prevention, 2009).

### Approaches

Promoting connectedness among individuals and within communities through modeling peer norms and enhancing community engagement can protect against suicide.

- **Peer norm approaches** seek to normalize prosocial behaviors/protective factors for suicide such as help-seeking, reaching out and talking to trusted adults, and peer connectedness. These approaches typically target youth and are delivered in school settings but can also be implemented in community settings.

- **Community engagement activities.** Community engagement is an aspect of social capital. Community engagement approaches may involve residents participating in a range of activities, including religious activities, community clean-up and greening activities, and physical exercise. These activities provide opportunities for residents to become more involved in the community and to connect with other community members, organizations, and resources, resulting in enhanced overall physical health, reduced stress, and decreased depressive symptoms, thereby reducing risk of suicide.

### Potential Outcomes

- Reduction in maladaptive coping attitudes and behaviors
- Increase in healthy coping attitudes and behaviors
- Increase in referrals for youth in distressed
- Increase help-seeking behaviors
- Positive perception of adult support

### Evidence

Current evidence suggests that peer norm approaches and community engagement can reduce risk factors associated with suicidal behaviors.

- **Peer norm approaches.** Evaluations show that programs such as *Sources of Strength* can improve school norms and beliefs about suicide that are created and disseminated by student peers. In a randomized controlled trial of *Sources of Strength* conducted with 18 high-schools (6 metropolitan, 12 rural), Wyman et al. (2010) found that the program improved peer leaders' adaptive norms regarding suicide, their connectedness to adults, and school engagement. Peer leaders were also more likely than controls to refer a suicidal friend to an adult. Among students, the intervention increased perceptions of adult support for suicidal youths and the acceptability of seeking help. Perception of adult support increased most in students with a history of suicidal ideation. Finally, trained peer leaders also reported a greater decrease in maladaptive coping attitudes compared with untrained leaders (Wyman et al., 2010).
- **Community engagement activities.** A vacant lot greening initiative was undertaken in Philadelphia between 1999 and 2008. Local residents and community members worked together to green 4,436 lots (or 7.8 million square feet) in 4 areas of the city. Researchers found significant associated reductions in community residents' self-reported stress levels and engagement in more physical exercise than residents in control vacant lot areas. Other benefits included reductions in firearm assaults and vandalism (Branas et al., 2011).

## Teach Coping and Problem-Solving Skills

### Rationale

Building life skills prepares individuals to successfully tackle every day challenges and adapt to stress and adversity. Life skills encompasses many concepts, but most often include coping and problem-solving skills, conflict resolution, and critical thinking. Life skills are important in shielding individuals from suicidal behaviors (World Health Organization, 2014). Suicide prevention programs that focus on life and social skills training are drawn from social cognitive theories (Bandura, 1986), surmising that individuals who engage in suicidal behavior is attributed to either direct learning, modeling, and environmental and individual (e.g. hopelessness) characteristics. The literature linking life skills and suicide is robust--- The inability to employ adequate coping strategies to cope with immediate stressors or identify and find solutions for problems have been characterized among suicide attempters (Pollock & Williams, 2004). Treatments that include bolstering problem skills (Goldsmith, Pellmar, Kleinman, & Bunney, 2002) and include problem-solving techniques (Ghahramanlou-Holloway, Bhar, Brown, Olsen, & Beck, 2012; Townsend et al., 2001) appear to reduce suicidal ideation and attempts more effectively. Prevention programs focused on teaching these skills target youth, parents and families and have been used with both universal and at-risk populations. While many do not target suicidal behaviors directly, these programs strive to train youth and parents important life skills to offset the underlying vulnerabilities that contribute to engaging in high risk behaviors early in life.

### Approaches

Current evidence provides support for the following two approaches:

- **Social emotional learning programs** focus on developing and strengthening communication and problem-solving skills, emotion regulation, conflict resolution, help seeking and coping skills. These approaches address a range of risk and protective factors for suicidal behavior. They provide children and youth with skills to resolve problems in relationships, school, and with peers, and help youth to address other negative influences (e.g., substance use) associated with suicide. These approaches are typically delivered to all students in a particular grade or school, although some programs also focus on groups of students considered to be at high-risk for suicide. Opportunities to practice and reinforce skills are an important part of programs that work (Herman, Borden, Reinke, & Webster-Stratton, 2011).
- **Parenting skill and family relationship programs** are designed to strengthen parenting skills, enhance positive parent-child interactions, and improve children's behavioral and emotional skills and abilities. Several parenting and family relationship programs have been shown in rigorous evaluations to improve resilience and reduce risk factors for various behaviors, including

ones closely related to suicide, such as depression, internalizing behaviors, and substance abuse (M. S. Knox, Burkhart, & Hunter, 2010).

### Potential Outcomes

- Reduction in suicide attempts and suicide ideation
- Enhanced knowledge of risk and protective factors associated with suicide
- Reduction in suicide risk behaviors (i.e., depression, anxiety, conduct problems, substance abuse)
- Improve and normalize help-seeking behavior
- Enhance social competence and emotional regulation skills
- Enhance problem-solving and conflict management skills

### Evidence

There are several programs with evidence that support teaching social, emotional and parenting skills to reduce suicidal behaviors and associated risk factors.

- **Social emotional learning programs.** The *Youth Aware of Mental Health Program (YAM)* is a program developed for teenagers that uses interactive dialogue and role-playing to teach adolescents about the risk and protective factors associated with suicide (including knowledge about depression and anxiety) and enhances their problem-solving skills for dealing with adverse life events, stress, school and other problems. The program includes 3 hours of role-play sessions and interactive workshops combined with a booklet that students can keep, educational posters displayed in classroom, and interactive lectures about mental health at the beginning and end of the program (Wasserman et al., 2014). In a cluster-randomized controlled trial of YAM conducted across 10 European Union countries and 168 schools, students participating in the YAM program were significantly less likely to have an incident suicide attempt (OR 0.45, 95%CI 0.24–0.85;  $p=0.014$ ) and severe suicidal ideation (0.50, 0.27-0.92;  $p=0.025$ ) at the 12-month follow-up compared to the control group. Additionally, related to severe suicide ideation, in the YAM group absolute risk fell by 0.50% and RR fell by 49.6% (Wasserman et al., 2014).

*Signs of Suicide (SOS)* is another school-based prevention program for students aged 13-17. The program includes guided classroom discussions about suicide and depression. As part of the program, students are screened for depression and suicide risk and referred for professional help as indicated. The program is designed to increase knowledge about suicide and risk factors associated with suicidal behavior as well as improve and normalize help-seeking behavior (Schilling, Aseltine, & James, 2016). In a randomized controlled trial, SOS was shown to reduce self-reported suicide attempts at 3-months post intervention among

participating students compared to control students. The SOS program also increased students' knowledge of how to get help for themselves or friends for depression and/or suicidal thoughts, and favorable attitudes toward help-seeking. SOS participants with a lifetime history of suicide attempt were also less likely to report planning a suicide in the 3 months following the program compared to lower-risk participants (Schilling et al., 2016).

Finally, the *Good Behavior Game (GBG)* is a classroom-based program for elementary school children aged 6-10; it represents an example of upstream suicide prevention programming. The program uses a team-based behavior management strategy that promotes good behavior by setting clear expectations for good behavior and consequences for maladaptive behavior. The goal of the GBG is to create an integrated classroom social system that is supportive of all children being able to learn with little aggressive or disruptive behavior (Wilcox et al., 2008). In an outcome evaluation of the GBG, first graders assigned to GBG reported half the adjusted odds of suicidal ideation and suicide attempts. The beneficial effect of the program was consistent for suicidal ideation regardless of whether baseline covariates were included. The GBG effect on attempts was less robust in some adjusted models including caregiver mental health. In the second cohort of GBG students, neither suicidal ideation nor suicide attempts were significantly different between GBG and the control interventions (Wilcox et al., 2008). This finding likely arose due to the lack of implementation fidelity and pointed to the need for GBG to be delivered with precision, consistency, and teacher support. GBG was also found to be associated with reduced risk of later substance abuse, a risk factor for suicide (Kellam et al., 2008).

- **Parenting skill and family relationship programs.** Parenting and family skills training approaches have shown promising impacts in preventing key risk factors associated with suicide. For example, the *Incredible Years (IY)* is a comprehensive group training program for parents, teachers and children designed to reduce conduct and substance abuse problems, two important suicide risk factors, in youth by improving protective factors such as responsive and positive parent-teacher-child interactions and relationships, emotion self-regulation and social competence (all protective factors for suicide) (Herman et al., 2011). The program includes 9- 20 sessions offered in community-based settings (e.g., religious, recreation centers, mental health treatment centers, and hospitals). Several studies have demonstrated the effect of the IY program on reducing internalizing symptoms, such as anxiety and depression, and child conduct problems (C. H. Webster-Stratton, Reid, & Beauchaine, 2011; Webster-Stratton, Jamila Reid, & Stoolmiller, 2008). The program is also associated with improved problem-solving and conflict management; these skills were maintained at 1-year follow-up (Reid, Webster-Stratton, & Hammond, 2003; C. Webster-Stratton & Hammond,

1997; C. Webster-Stratton, Reid, & Hammond, 2001). The program demonstrated greater benefits as the dosage of the intervention increased (Herman et al., 2011).

Additionally, *Strengthening Families 10-14* is a program that involves sessions between parents, youth, and family with the goal of improving parents' skills for disciplining, managing emotions and conflict, and communicating with their children; promoting youths' interpersonal and problem-solving skills; and creating family activities to build cohesion and positive parent-child interactions. The premise of the program is that developing these skills for both parents and children will reduce internalizing behavior and adolescent substance abuse, two important risk factors for suicide (Spoth, Gyll, & Day, 2002). *Strengthening Families* has been shown to decrease externalizing behaviors, alcohol use, and drug use among youth participants and reductions in depression, alcohol use, and drug use among participating families (Spoth et al., 2002).

## Identify and Support People At-Risk

### Rationale

In order to decrease suicide, attention to people at increased or high risk is necessary as these individuals tend to experience suicidal behavior at higher than average rates. These vulnerable or disadvantaged populations include, but are not limited to, individuals with lower socio-economic status or who are living with a mental health problem; people who have attempted suicide previously, individuals who are institutionalized, have been victims of violence, or are homeless; and members of certain ethnic minority groups. Supporting these vulnerable groups requires proactive case finding along with access to, and retention in, mental health services. Finding effective ways of identifying at-risk or vulnerable groups, customizing services to make them accessible and maintaining care remain key challenges. For example, simply improving services does not guarantee that those services will be used by those most in need of them, nor will it necessarily increase the number of people who follow treatments that are recommended. People who are disadvantaged face social and economic issues that may adversely affect their ability to respond to the treatments or advice that are offered.

### Approaches

The following three approaches focus on identifying and supporting people at increased risk.

- **Gatekeeper training** is designed to train teachers, coaches, providers and others in the community to identify people who may be at risk of suicide and to respond effectively, including facilitating treatment seeking and support services. Gatekeeper training is typically implemented in schools to identify at-risk youth and within health care settings to identify adults (and youth).
- **Screening combined with care management and overall continuity of care** has been used in primary care and behavioral health care settings to assure that people who may be at high-risk of suicide are identified and receive ongoing treatment as needed, particularly after inpatient discharge and other transitions within the healthcare system so they don't 'slip through the cracks'. These approaches typically employ screening for depression and/or suicide combined with collaborative treatment planning between patients and their providers and patient follow-up.
- **Crisis intervention.** These approaches provide support and referral services, typically by connecting a person in crisis (or a friend or family member of someone at-risk) to trained volunteers and/or professional staff via telephone hotline, online chat, or text messaging. Crisis intervention approaches are intended to impact key risk factors for suicide, including feelings of depression, hopelessness, and subsequent mental health care utilization. Like means reduction,

crisis interventions can put space or time between an individual who may be considering suicide and harmful behavior.

### Potential Outcomes

- Reduction in suicide attempts
- Reduction in suicide deaths
- Increased identification of individuals at-risk for suicidal behavior
- Increased at-risk individuals in treatment
- Increased community members trained to identify at-risk individuals
- Increased referrals for health care

### Evidence

There is evidence that community gatekeeper programs are successful in reducing suicides and suicide attempts but the efforts must be maintained (Substance Abuse and Mental Health Services Administration, 2014). However, there is limited evidence for effectiveness screening programs, but at the same time, standard principles for public health screening make them promising (Pena & Caine, 2006). The number of studies evaluating crisis intervention services is limited, but a few studies do indicate that those who use the hotline services have decreased suicidal thoughts and behavior.

- **Gatekeeper training.** One example of gatekeeper training is the *Mental Health First Aid (MHFA)* program. This program is designed for the lay public and consists of three weekly sessions of three hours each. Participants learn the symptoms of people in mental health crises and/or in the early stages of mental health problems (i.e., those experiencing suicidal thoughts and behavior, acute stress reaction, panic attacks and acute psychotic behavior, and depression, anxiety, and psychotic disorders), possible risk factors, and where and how to get evidence-based effective help (Kitchener & Jorm, 2004). In a randomized controlled trial of 300 participants of *MHFA*, the intervention group reported greater confidence in providing help to others, greater likelihood of advising people to seek professional help, improved concordance with health professionals about treatments, and decreased stigmatizing attitudes. Additionally, the intervention resulted in improved mental health of the participants themselves. All results were statistically significant at  $p < .05$ . (Kitchener & Jorm, 2004). Additional research rigorously evaluating *MHFA* for its impact on the first aid recipients themselves and suicidal behavior is needed (Kitchener & Jorm, 2006).

Gatekeeper training has also been a core part of all *Garret Lee Smith (GLS) Suicide Prevention Program* which is in place in 49 states and 48 tribes. A multi-site evaluation assessed the

connection between community gatekeeper training and a reduction of suicide attempts and deaths by comparing the change in suicide mortality rates and nonfatal suicidal behavior among the population aged 10-24 in counties implementing *GLS* trainings, with the trajectory observed in similar counties that did not implement these trainings. Counties implementing *GLS* trainings had significantly lower youth suicide rates the year following the training implementation (-1.07,  $p=.03$ ) (Walrath, Garraza, Reid, Goldston, & McKeon, 2015). This finding represents a decrease of 1 suicide death per 100,000 10 to 24 year olds or the avoidance of approximately 237 deaths in this age group between 2007 and 2010. Counties implementing *GLS* program activities also had significantly lower suicide attempt rates among youths 16 to 23 years of age in the year following implementation of the *GLS* program than did similar counties that did not implement *GLS* program activities (4.9 fewer attempts per 1000 youths [95% CI, 1.8-8.0 fewer attempts per 1000 youths];  $p = .003$ ; (Godoy Garraza, Walrath, Goldston, Reid, & McKeon, 2015)). More than 79 000 suicide attempts may have been averted during the period studied following implementation of the *GLS* program.

- **Screening combined with care management and overall continuity of care.** The *Henry Ford Perfect Depression Care* program was the pre-cursor to *Zero Suicide*, and its overall goal was to eliminate suicide. More broadly, though, the aim was to completely redesign depression care delivery to achieve breakthrough improvement in quality and safety by focusing on six aims: effectiveness, safety, patient centeredness, timeliness, efficiency, and equity among patients. The program developed concrete measures to assess progress on each of these aims and began with screening and assessment of each patient for suicide risk with coordinated continuous follow-up care system wide (C. E. Coffey, 2006). An examination of the impact of the *Henry Ford Perfect Depression Care (Pre-cursor to Zero Suicide)* program found that there was a dramatic and statistically significant decrease in the rate of suicide between the baseline years prior to the intervention (1999 and 2000) to the intervention years (2002-2009). During this time period, the suicide rate fell 82% (C. E. Coffey, 2006; C. E. Coffey, Coffey, & Ahmedani, 2013). Further, suicide rates also declined among HMO members who participated in targeted suicide prevention efforts and received mental health specialty services. However, for those HMO members who accessed only general medical services as opposed to specialty mental health services, the suicide rate increased (M. Coffey, Coffey, & Ahmedani, 2015).
- **Crisis intervention.** Suicide prevention hotlines are one way to provide crisis intervention. In an evaluation of the effectiveness of the *National Suicide Prevention Lifeline (NSPL)* to prevent suicide, 1,085 suicidal individuals who called the hotline completed a standard risk assessment for suicide, and 380 of those completed a follow-up assessment between 1 and 52 days after the initial assessment. Researchers found that over half of the initial sample were seriously considering suicide when they called, and they had a plan for their suicide. Researchers also

found that participants experienced significant decreases in suicidality over the course of the telephone session, and that levels of hopelessness and psychological pain continued to decrease after their initial call (Gould, Kalafat, Harrismunfakh, & Kleinman, 2007).

In another study, this time employing a randomized controlled trial, Gould, Cross, Pisani, Munfakh, and Kleinman (2013) assessed the impact of the *Applied Suicide Intervention Skills Training (ASIST)*, a widely implemented training program that helps hotline counselors, emergency workers, and other gatekeepers to identify and connect with suicidal individuals, understand their reasoning for living and dying, and assist with safely connecting those in need to available resources. The training was evaluated across the NSPL network of hotlines over the period 2008-2009. Using data from 1,410 suicidal individuals who called 17 Lifeline centers, researchers found that compared to callers who spoke to counselors that received the usual care training, individuals who spoke with counselors trained in *ASIST* were significantly more likely to feel less depressed, less suicidal, less overwhelmed, and more hopeful by the end of their call to the hotline. Counselors trained in *ASIST* were also more skilled at keeping callers on the phone longer and establishing a connection with them. However, training in *ASIST* did not result in more comprehensive suicide risk assessments than usual care training (Gould et al., 2013).

## Intervene to Lessen Harms and Prevent Future Risk

### Rationale

Individuals who have experienced mental health challenges, suicidal ideation, and/or who have made suicide attempts and/or have engaged in non-suicidal self-injury are at increased risk of suicide (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012). Risk of suicide can also increase among those who have lost a friend, family member, co-worker, or other acquaintance to suicide (Pitman, Osborn, King, & Erlangsen, 2014). Exposure to sensationalized or uninformed reporting regarding on suicide may heighten the risk of suicide among vulnerable individuals and can inadvertently contribute to suicide contagion (Etzersdorfer & Sonneck, 1998; Niederkrotenthaler & Sonneck, 2007).

### Approaches

A broad array of approaches to lesson harms and reduce future risk of suicide among those at increased risk include the provision of mental health care and improved continuity of care, improving linkage to care through active post-discharge planning and follow-up that decreases barriers to ongoing therapeutic support, increasing connectedness to supportive others, addressing bereavement, and framing communications to emphasize resilience, decrease negative affect, and to prevent contagion.

- **Treatment for people at-risk of suicide** typically includes various forms of psychotherapy delivered by licensed providers to help individuals with mental health problems and other risk factors for suicide with problem-solving, impulsivity and emotion regulation.
- **Treatment to prevent re-attempts.** These approaches typically include follow-up contact and use diverse modalities (e.g., home visits, mail, telephone, e-mail) to engage recent suicide attempt survivors in continued treatment to prevent re-attempts. Treatment may focus on improved coping skills, mindfulness, and other emotional regulation skills, and may include case management home visits to increase adherence to treatment and continuity of care; and one-on-one interpersonal therapy and/or group therapy. Approaches that engage and connect attempters to peers and providers are especially important because many attempters do not present to aftercare; 12%-25% reattempt within a year, and 3%-9% of attempt survivors die by suicide within 1 to 5 years of their initial attempt (Inagaki et al., 2015)
- **Postvention** approaches are implemented *after* a suicide has taken place and may include debriefing sessions, counseling, and/or bereavement support groups for surviving friends and family members/loved ones. These programs have not typically been evaluated for their impact on suicide or suicidal behavior but may reduce survivors' guilt, feelings of depression, and complicated grief (Szumilas & Kutcher, 2011).

- **Safe messaging following a suicide.** The manner in which information on a recent suicide is communicated to the public (e.g. school assemblies, mass media, social media) can heighten the risk of suicide among vulnerable individuals and can inadvertently contribute to suicide contagion. Therefore, responsible and safe reporting may help prevent suicide and/or suicide contagion.

### Potential Outcomes

- Reduction in mental health-related sequelae
- Increase connectedness
- Improved coping skills
- Improved messaging following suicide
- Reduction in re-attempts

### Evidence

The evidence addressing strategies to lesson harm and prevent future risk of suicide includes the evaluation of effects of specific approaches on risk and protective factors as well as suicide-related mortality. However, because the evaluation of suicide-related mortality requires large sample sizes and extended follow-up, much of the evidence in this area primarily focuses on risk and protective factors.

- **Treatment for people at-risk of suicide.** There are a number of treatments with evidence of impact on risk and protective factors for suicide. One example is the *Improving Mood – Promoting Access to Collaborative Treatment (IMPACT)* program. *IMPACT* aims to prevent suicide among older primary care patients by reducing suicide ideation and depression in primary care settings. It facilitates the development of a therapeutic alliance, a personalized treatment plan that includes patient preferences, as well as proactive follow-up (biweekly during an acute phase and monthly during continuation phase) by a depression care manager (Hunkeler et al., 2006). The program has been shown to significantly improve quality of life, and to reduce functional impairment, depression and suicidal ideation over 24-months of follow-up (Hunkeler et al., 2006; Unutzer et al., 2006) relative to patients who received care as usual.

Another example is *Collaborative Assessment and Management of Suicidality (CAMS)*, which is a therapeutic approach for suicide-specific assessment and treatment of patient's suicide risk. This flexible approach can be used across treatment settings and clinician theoretical orientations and involves the clinician and patient working together in an interactive assessment process to develop patient-specific treatment plans. *CAMS* sessions are collaborative and involve constant

patient about what is and is not working with the ultimate goal of enhancing the therapeutic alliance and increasing treatment motivation in the suicidal patient. CAMS been tested and supported in 6 correlational studies (Jobes, 2012), in a variety of inpatient and outpatient settings and in one RCT with several additional RCTs under way. CAMS has been associated with significant improvements in suicidal ideation, overall symptom distress, and feelings of hopelessness at 12 month follow-up among a community-based sample of suicidal outpatients. (Comtois et al., 2011).

Other examples include *Dialectical Behavioral Therapy (DBT)* and *Attachment-Based Family Therapy (ABFT)*. DBT is a multicomponent therapy for individuals at high risk for suicide and who may struggle with impulsivity and emotional regulation. The components of DBT include individual therapy, group skills training, between-session telephone coaching and a therapist consultation team. In a randomized controlled trial of women with recent suicidal or self-injurious behavior, those receiving DBT were half as likely to make a suicide attempt at two-year follow-up than women receiving community treatment (23% vs 46%), required less hospitalization for suicide ideation, and had lower medical risk across all suicide attempts and self-injurious acts combined (Linehan et al., 2006).

ABFT is a program for adolescents aged 12-18 and is designed to treat clinically diagnosed major depressive disorder, eliminate suicidal ideation, and reduce dispositional anxiety (Diamond et al., 2010). A randomized controlled trial of ABFT found that suicidal adolescents assigned to ABFT experienced significantly greater improvement in suicidal ideation over 24 weeks of follow-up than did adolescents assigned to enhanced usual care (-4.37 vs. -2.34;  $p = .001$ ;  $d=0.97$ ). Additionally, a higher percentage of ABFT participants reported no suicidal ideation in the week prior to assessment at 12 weeks than did adolescents receiving enhanced usual care (69.2% vs. 34.6%;  $p = .01$ ; OR= 4.25) and at 24 weeks (82.1% vs. 46.2%;  $p = .006$ ; OR=5.37) (Diamond et al., 2010).

- **Treatment to prevent re-attempts.** Several strategies that aim to prevent re-attempts have demonstrated impact on reducing suicidal behavior. For example, *Emergency Department Brief Intervention with Follow-up Visits* is a program that involves a one-hour discharge information session that addresses suicidal behavior, distress, risk and protective factors, alternatives to suicidal behavior, and referral options, combined with nine follow-up contacts over 18-months (at 1, 2, 4, 7, 11 weeks and 4, 6, 12, 18 months). Follow-up contacts are either conducted by phone or through home visits according to a specific time line for up to 18-months. A randomized controlled trial that enrolled suicide attempters from eight hospital emergency departments in five culturally different sites found that a brief intervention combined with 9 follow-up visits over 18-months was associated with significantly fewer deaths from suicide relative to a treatment-

as-usual group (0.2% versus 2.2%, respectively;  $\chi^2 = 13.83$ ,  $P < 0.001$ ) (Fleischmann et al., 2008).

Another example of treatment to prevent re-attempts involves *active follow-up contact approaches* such as postcards, letters, and telephone calls, are intended to increase a patient's sense of connectedness with health care providers and decrease isolation. These approaches include expression of care and support and typically invite patients to reconnect with their provider. Contacts are made periodically (e.g., monthly or every few months in the first 12 months post-discharge with some programs continuing contact for 2 or more years). These approaches have been found in a meta-analysis conducted by Inagaki et al. (2015) to reduce reattempts by approximately 17% for up to 12 months post-discharge, however, the long-term effects of these approaches on reattempts has not yet been demonstrated. Also, because the number of trials and associated sample sizes included in this meta-analysis were small, it was not possible to determine the effect of active contact and follow-up approaches on death by suicide.

In a randomized controlled trial of post-crisis suicide prevention long-term follow-up contact approach, Motto and Bostrom (2001) found that patients who refused ongoing care but who were randomized to be contacted by letter four times per year had a lower rate of suicide over two years of follow-up than did patients in the control group who received no further contact. Other studies have also shown post-crisis letters and coping cards to be protective against suicide ideation and attempts (Hassanian-Moghaddam, Sarjami, Kolahi, & Carter, 2011; Wang et al., 2016).

Finally, *Cognitive Behavior Therapy for Suicide Prevention (CBT-SP)* is an example of a therapeutic approach to prevent re-attempts. It uses a risk reduction, relapse prevention approach that includes an analysis of proximal risk factors and stressors (e.g., relationship problems, school or work-related difficulties) leading up to and following the suicidal event; safety plan development; skill building; and psychoeducation. *CBT-SP* also has family skill modules focused on family support and communication patterns as well as improving the family's problem solving skills. A randomized controlled trial found of *CBT-SP* found that 10-session outpatient cognitive therapy designed to prevent repeat suicide attempts resulted in a 50% reduction in the likelihood of a suicide reattempt among adults who had been admitted to an emergency department for a suicide attempt relative to treatment as usual (Brown et al., 2005).

- **Postvention** programs are implemented with the goal of providing support to survivors of suicide to reduce their own risk of suicide. One example of a postvention program, *StandBy Response Service (StandBy)*, provides clients with face-to-face outreach and telephone support through a professional crisis response team. Site coordinators develop customized case management plans, referring clients to other existing community services matched to their needs (Visser, Comans, &

Scuffham, 2014). In a study by Visser et al. (2014), *StandBy* clients were significantly less likely to be at high risk for suicidality than a suicide bereaved comparison group who had not had contact with the *StandBy* program (48% and 64% respectively,  $p = 0.005$ ). Additionally, research suggests that active postvention approaches in which outreach to suicide survivors occurs at the scene of a suicide is associated with intake into treatment sooner, greater attendance at support group meetings, and attendance at more meetings compared to passive postvention (versus passive approaches where survivors self-refer for services) (J. Cerel & Campbell, 2008).

- **Safe messaging following a suicide.** Safe messaging after a suicide can help assure that reporting of the event is done in such a way to reduce risk to consumers of news media and other messaging who may be particularly vulnerable. One way to ensure safe messaging following a suicide is to encourage that reporters adhere to *media guidelines for reporting on suicides*. Reports that are both inclusive of suicide prevention messages, stories of hope and resilience, risk and protective factors, and links to helping resources (e.g., hotline) and that avoid sensationalizing events or reducing suicide to one cause can help reduce the likelihood of suicide contagion. The most compelling evidence supporting the effect of *media guidelines* on reduction in suicides comes from Austria. After a sharp increase in suicides on the Viennese subway, media guidelines were introduced and an interrupted time series design was used to evaluate the national impact of the guidelines on subsequent suicides. Changes in the quality and quantity of media reporting resulted in a reduction of 81 suicides annually (95% confidence interval: -149 to -13;  $t = -2.32$ ,  $df = 54$ ,  $p < 0.024$ ) in the Viennese subway system (Niederkrotenthaler & Sonneck, 2007)

## Sector Involvement

Public health can play an important and unique role in addressing suicide. Public health agencies, which typically place prevention at the forefront of efforts and work to create broad population-level impact, can bring critical leadership and resources to bear on this problem. For example, these agencies can serve as a convener, bringing together partners and stakeholders to plan, prioritize, and coordinate suicide prevention efforts. Public health agencies are also well positioned to collect and disseminate data, implement preventive measures, evaluate programs, and track progress. Although public health can play a leadership role in preventing suicide, the strategies and approaches outlined in this technical package cannot be accomplished by the public health sector alone.

Other sectors vital to implementing this package include, but are not limited to, education, government (local, state, and federal), social services, health services, business/labor, justice, housing, media, and organizations that comprise the civil society sector such as faith-based organizations, youth-serving organizations, foundations, and other non-governmental organizations. Collectively, these sectors can make a difference in preventing suicide by impacting the various contexts and underlying risks that contribute to suicide.

The strategies and approaches described in this technical package are summarized in Appendix A along with the relevant sectors that are well positioned to lead implementation efforts.

[Linda to insert text specific to the strategies and approaches]

Regardless of strategy, action by many sectors will be necessary for the successful implementation of this package. In this regard, all sectors can play an important and influential role in creating safe and protective environments where individuals who are at high risk of suicide can easily access the mental healthcare and services they need.

## Monitoring and Evaluation

Monitoring and evaluation are necessary components of the public health approach to prevention. It is important to have timely and reliable data to monitor the extent of the problem and to evaluate the impact of prevention efforts. Data are necessary for program implementation; planning, implementation, and assessment all rely on accurate measurement of the problem.

Surveillance data helps researchers and practitioners track changes in the burden of suicide. Surveillance systems exist at the federal, state, and local levels. It is important to assess the availability of surveillance data and data systems across these levels to identify and address gaps in the systems. CDC's National Vital Statistics System and the National Violent Death Reporting System (NVDRS) are examples of surveillance systems that provide data on deaths from suicide. NVDRS, for example, is a state-based surveillance system that combines data from death certificates, law enforcement reports, and coroner or medical examiner reports to provide detailed information on the circumstances of violent deaths, including suicide, which can assist communities in guiding prevention approaches (Blair, Fowler, Jack, & Crosby, 2016). The National Electronic Injury Surveillance System-All Injury Program (NEISS-AIP) provides nationally representative data about all types and causes of nonfatal injuries treated in U.S. hospital emergency departments, and can be used to assess national rates of, and trends in, self-harm injuries by cause (e.g., falls, poisoning, etc.), age, race/ethnicity, sex, disposition (where the injured person goes when released from the Emergency Department).

In addition to information on deaths and nonfatal injuries, there are also surveillance systems that provide national, state, and some local estimates of suicidal behavior. The Youth Risk Behavior Surveillance System (YRBSS) collects information from a nationally representative sample of 9-12 grade students and is a key resource in monitoring health-risk behaviors among youth, including whether youth have seriously considered attempting suicide, attempted suicide, made a plan, or required treatment by a doctor or nurse for a suicide attempt that resulted in an injury, poisoning, or overdose (Brener et al., 2013). The YRBSS data are obtained from a national school-based survey conducted by CDC as well as school-based state, territorial, tribal, and large urban school district survey conducted by education and health agencies. The National Survey on Drug Use and Health (NSDUH) is an annual nationwide survey of individuals aged 12 years and older that provides national and state-level estimates of drug use and mental health-related issues, including suicide ideation and suicide attempts.

It is also important at all levels (local, state, and federal) to address gaps in responses, track progress of prevention efforts and evaluate the impact of those efforts, including the impact of this technical package. Evaluation data, produced through program implementation and monitoring, is essential to provide information on what does and does not work to reduce rates of suicide and its associated risk and protective factors. Theories of change and logic models that identify short, intermediate, and long-term outcomes are an important part of program evaluation.

The evidence-base for suicide prevention has advanced greatly over the last few decades. However, additional research is needed to understand the impact of prevention programs on preventing suicide, as opposed to merely examining the effectiveness of programs to impact risk factors associated with suicide. More research is also needed to examine the effectiveness of upstream and community-level strategies to prevent suicide at the population level. Lastly, it will be important for researchers to test the effectiveness of combinations of the strategies and approaches included in this package. Most existing evaluations focus on approaches implemented in isolation. However, there is potential to understand the synergistic effects within a comprehensive prevention approach. Additional research is needed to understand the extent to which combinations of strategies and approaches result in greater reductions in suicide than individual programs, practices, or policies.

## Conclusion

Suicide is a serious public health problem whose rates have been on the rise for more than a decade and whose costs stretch well into the billions of dollars each year. And while suicide is a rare outcome statistically, its human impact has a ripple effect that is far-reaching. Each of us likely interacts with suicide survivors, those with lived experience, and those with thoughts of suicide, on a daily basis—at home, at work, and in our communities. Suicide and suicide attempts are therefore public health issues of societal concern. Fortunately, like many public health problems, suicide is preventable, and fortunately more is being done to prevent suicide than ever before, as evidenced by the work of the National Action Alliance for Suicide Prevention, the release of the first world report on suicide, more timely surveillance data, and critical mention in the President’s FY17 budget, to name just a few examples. Unfortunately and unlike most other public health problems, suicide still struggles against stigma, shame, and secrecy related to help-seeking, mental illness, being a survivor, or someone with lived experience; misplaced fear of asking someone about their risk of suicide (versus the fear and consequence of not asking), and fear of taking up certain strategies known to be effective but perhaps unpopular; misinformation about suicide preventability, and disproportionate funding given the public health burden. Suicide also struggles against the right degree of awareness where too much information, for example by well-meaning reporters and others, may actually do harm.

In an effort to continue pushing the field and society further towards prevention, this technical package includes strategies and approaches that ideally would be used in a comprehensive fashion, in combination—in a multi-level, multi-sectoral way. This technical package includes strategies and approaches targeting upstream prevention, e.g., social emotional learning for children and youth, as well as strategies focused more downstream, e.g., cognitive behavioral treatment to prevent re-attempts. It includes universal, selective, and indicated strategies, or strategies that focus on the whole population regardless of risk to strategies that focus on those groups at highest risk. Importantly, this technical package extends the bounds of the typical prevention strategies to consider approaches at the outer

levels of the social ecology, e.g., policies to stabilize housing and community engagement initiatives. In short, care and attention has been paid to all aspects of suicide prevention.

While the evidence base continues to be built, the collection of programs, policies, and practices laid out here are available for implementation now. And in keeping with good public health practice, the intent is that monitoring and evaluation will play a key role in that implementation. Moreover, as new evidence becomes available, this technical package can be refined to reflect the current state of the science.

In closing, and in keeping with a message of resilience as spoken by those with lived experience, ‘hope, help, and healing is possible.’

## Appendix A: Summary of Strategies and Approaches to Prevent Suicide

Strategy	Approach/Program, Practice or Policy	Best Available Evidence			Lead Sectors <sup>1</sup>
		Suicide	Suicide Attempts or Ideation	Other Risk/Protective Factors for Suicide	
Strengthen economic supports	Strengthen household financial security				
	Unemployment benefit programs	✓			Government (local, state, Federal)
	Housing stabilization policies				
	The National Neighborhood Stabilization Program			✓	Government (local, state, Federal)
Strengthen access to mental health care	Coverage of mental health conditions in health insurance policies				
	Mental Health Parity Laws	✓		✓	Government (state, Federal)  Health care
Establish protective environments	Reducing access to lethal means among persons at-risk				
	Intervening at hot spots	✓			Government (local, state, Federal)
	Safe storage practices		✓	✓	Public Health
	Organizational policies and culture				
	Together for Life	✓			Business/Labor

		Best Available Evidence			
	<i>US Air Force Suicide Prevention Program</i>	✓		✓	Government (local, state, Federal)  Business/Labor
	Community-based policies to reduce excessive alcohol use				
	<i>Alcohol outlet density</i>	✓		✓	Government (local, state, Federal)
Promote connectedness to protect against suicide	Peer norm approaches				
	<i>Sources of Strength</i>			✓	Public Health Social Services
	Community-engagement activities				
	<i>Greening vacant urban spaces</i>			✓	Public Health
Teach coping and problem- solving skills	Social emotional learning				
	<i>Youth Aware of Mental Health Program</i>		✓		Public Health
	<i>Signs of Suicide</i>		✓	✓	Education
	<i>Good Behavior Game</i>		✓	✓	
	Parenting skill and family relationship approaches				
	<i>The Incredible Years</i>			✓	Public Health  Education

		Best Available Evidence			
	<i>Strengthening Families 10-14</i>			✓	
Identify and support people at-risk	Gatekeeper training				
	<i>Mental Health First Aid</i>			✓	Public Health Healthcare Social Services
	Screening combined with care management				
	<i>Henry Ford Perfect Depression Care (Pre-cursor to Zero Suicide)</i>	✓		✓	Healthcare
	Crisis Intervention				
	<i>National Suicide Prevention Lifeline</i>		✓	✓	Public Health Social Services
	<i>Applied Suicide Intervention Skills Training</i>		✓	✓	
Treatment for people at risk of suicide					
<i>Improving Mood – Promoting Access to Collaborative Treatment (IMPACT)</i>		✓	✓	Healthcare Social Services	
<i>Collaborative Assessment and Management of Suicidality (CAMS)</i>		✓	✓		

		Best Available Evidence			
Intervene to lessen harms and prevent future risk	<i>Dialectical Behavioral Therapy</i>		✓	✓	
	<i>Attachment-Based Family Therapy</i>		✓		
	Treatment to prevent re-attempts				
	<i>ED Brief Intervention with Follow-up Visits</i>	✓			Healthcare
	<i>Active follow-up contact approaches</i>	✓	✓		
	<i>CBT for Suicide Prevention</i>				
	Postvention				
	<i>StandBy Response Service</i>		✓		Healthcare
	Safe messaging following a suicide				
	<i>Media Guidelines</i>	✓			Public Health

<sup>1</sup>This column refers to the lead sectors well positioned to bring leadership and resources to implementation efforts. For each strategy, there are many other sectors such as non-governmental organizations that are instrumental to prevention planning and implementing the specific programmatic activities.

## Overview

This technical package represents a select group of strategies based on the best available evidence to help communities and states sharpen their focus on prevention activities with the greatest potential to prevent suicide. These strategies include strengthening economic supports; strengthening access to mental health care; creating protective environments; promoting connectedness; teaching coping and problem-solving skills; identifying and supporting people at-risk; and intervening to lessen harms and prevent future risk. The strategies represented in this package include those with a focus on preventing suicide from happening in the first place as well as approaches to lessen the immediate and long-term harms of suicidal behavior for individuals, families, communities, and society. The strategies in the technical package support the goals and objectives of the National Strategy for Suicide Prevention and the National Action Alliance for Suicide Prevention's priority to strengthen community-based prevention. Commitment, cooperation, and leadership from numerous sectors, including public health, education, justice, health care, social services, business/labor, and government can bring about the successful implementation of this package.

### What is a Technical Package?

A technical package is a compilation of a core set of strategies to achieve and sustain substantial reductions in a specific risk factor or outcome (Frieden, 2014). Technical packages help communities and states prioritize prevention activities based on the best available evidence. This technical package has three components. The first component is the **strategy** or the preventive direction or actions to achieve the goal of preventing suicide. The second component is the **approach**. The approach includes the specific ways to advance the strategy. This can be accomplished through *programs, policies, and practices*. The approaches included come primarily from studies based in the United States. The **evidence** for each of the approaches in preventing suicide or its associated risk factors is included as the third component. This package is intended as a resource to guide and inform prevention decision-making in communities and states.

### Preventing Suicide is a Priority

Suicide, as defined by the Centers for Disease Control and Prevention (CDC), is part of a broader class of behavior called *self-directed violence*. Self-directed violence refers to behavior directed at oneself that deliberately results in injury or the *potential* for injury (Crosby, Ortega, & Melanson, 2011). Self-directed violence may be *suicidal* or *non-suicidal* in nature. For the purposes of this document, we refer only to behavior where suicide is intended:

- **Suicide** is a death caused by self-directed injurious behavior with any intent to die as a result of the behavior.

- **Suicide attempt** is defined as a *non-fatal* self-directed and potentially injurious behavior with any intent to die as a result of the behavior. A suicide attempt may or may not result in injury.

**Suicide is highly prevalent.** Suicide presents a major challenge to public health in the United States and worldwide. It contributes to premature death, morbidity, lost productivity, and health care costs (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014). In 2014 (the most recent year of available death data), suicide was responsible for 42,773 deaths in the U.S., which is approximately one suicide every 12 minutes (Centers for Disease Control and Prevention, 2016d). In 2014, suicide ranked as the 10th leading cause of death and has been among the top 12 leading causes of death since 1975 in the U.S (Centers for Disease Control and Prevention, 2016d). Overall suicide rates have increased 24% from 1999 to 2014 (Curtin, Warner, & Hedegaard, 2016). Suicide is a problem throughout the life span; it is the second leading cause of death among those aged 10–19 years, also second among persons in their 20s and 30s; it is the fourth leading cause among persons in their 40s and seventh among persons in their 50s (Centers for Disease Control and Prevention, 2016d).

Suicides reflect only a portion of the problem (Crosby, Han, Ortega, Parks, & Gfroerer, 2011). Substantially more people are hospitalized as a result of nonfatal suicidal behavior (i.e. suicide attempts) than are fatally injured, and an even greater number are either treated in ambulatory settings (e.g., emergency departments) or not treated at all (Crosby, Han, et al., 2011). For example, during 2014, among adults aged 18 years and older, for every one suicide there were 9 adults treated in hospital emergency departments for self-harm injuries, 27 who reported making a suicide attempt, and over 227 who reported seriously considering suicide (i.e. ideation) (Ferdon et al., In press).

**Suicide is associated with several risk and protective factors.** Suicide, like other human behaviors, is complex with no single determining cause. Instead, suicide occurs in response to multiple biological, psychological, interpersonal, environmental and societal influences that interact with one another, often over time. The social-ecological model-- encompassing multiple levels of focus from the individual, relationship, community, and societal-- is a useful framework for viewing and understanding suicide risk factors identified in the literature (Dahlberg & Krug, 2002). Risk and protective factors for suicide exist at each level. For example, risk factors include:

- **Individual level:** History of depression and other mental illnesses, alcohol and drug abuse, previous suicide attempt, violence victimization, genetic and biological determinants, hopelessness
- **Relationship level:** High conflict or violent relationships, sense of isolation and lack of social support, family/loved one's history of suicide, financial and work stress
- **Community level:** Inadequate community connectedness, barriers to health care (e.g., lack of access to providers and medications)

- **Societal level:** Availability of lethal means of suicide, unsafe media portrayals of suicide, stigma associated with help-seeking and mental illness (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014).

It is important to recognize that the vast majority of individuals who are depressed or who have other risk factors noted, do *not* die by suicide. Furthermore, the relevance of each risk factor can vary by age, race, gender, sexual orientation, residential geography, and socio-cultural and economic status (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014).

Protective factors, or those influences that guard *against* the risk for suicide, can also be found across the different levels of the social-ecological model. Protective factors identified in the literature include: effective coping and problem solving skills, moral objections to suicide, strong and supportive relationships with partners, friends, and family; connectedness to school, community and other social institutions; availability of quality and ongoing physical and mental health care, and reduced access to lethal means (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014). These protective factors can either counter a specific risk factor or guard against a number of risks associated with suicide.

**Suicide is connected to other forms of violence.** Suicide and other forms of violence often share some of the same root causes (Butchart, Phinney, Check, & Villaveces, 2004; Klevens, Simon, & Chen, 2012). For example, in neighborhoods where there is low social cohesion, or where residents don't support and trust each other, people are at higher risk for suicide (Desai, Dausey, & Rosenheck, 2005) as well as perpetration of child maltreatment (Coulton, Crampton, Irwin, Spilsbury, & Korbin, 2007; Freisthler, Merritt, & LaScala, 2006), teen dating violence (Capaldi, Knoble, Shortt, & Kim, 2012), intimate partner violence (Pinchevsky & Wright, 2012), and youth violence (Sampson, Morenoff, & Gannon-Rowley, 2002). Additionally, a lack of economic opportunities and unemployment are associated with suicide (Luo, Florence, Quispe-Agnoli, Ouyang, & Crosby, 2011; Reeves et al., 2012), as well as perpetration of child maltreatment (D. Runyan, Wattam, Ikeda, Hassan, & Ramiro, 2002), intimate partner violence (Heise & Garcia-Moreno, 2002; Pinchevsky & Wright, 2012), sexual violence (Centers for Disease Control and Prevention, 2016c) and youth violence (Wilson, 2011). Other shared risk factors for suicide and violence occur at the individual level and include substance abuse, mental health problems, witnessing violence, and a lack of problem-solving skills (Centers for Disease Control and Prevention, 2016a, 2016c, 2016e; U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012).

Just as risk factors may be shared across suicide and violence, so too may protective factors overlap. For example, connectedness increases individual's and communities' resilience to suicide and other forms of violence, including connectedness to one's community (Basile, Hamburger, Swahn, & Choi, 2013; Borowsky, Hogan, & Ireland, 1997; Centers for Disease Control and Prevention, 2016b; Coulton et al.,

2007; Kleiman, Riskind, Schaefer, & Weingarden, 2012; Pinchevsky & Wright, 2012; Widome, Sieving, Harpin, & Hearst, 2008), school (Basile, Espelage, Rivers, McMahon, & Simon, 2009; Capaldi et al., 2012; Carter, McGee, Taylor, & Williams, 2007; DeGue et al., 2013; Hong, Kral, Espelage, & Allen-Meares, 2012; Losel & Farrington, 2012), family (Capaldi et al., 2012; Centers for Disease Control and Prevention, 2016a; Elgar, Craig, Boyce, Morgan, & Vella-Zarb, 2009; Maimon, Browning, & Brooks-Gunn, 2010; Resnick, Ireland, & Borowsky, 2004), caring adults (Capaldi et al., 2012; Losel & Farrington, 2012; Maimon et al., 2010), and pro-social peers (Capaldi et al., 2012; Losel & Farrington, 2012).

**The health and economic consequences of suicide are substantial.** Suicide and suicide attempts have far-reaching consequences for individuals, families, and communities (Dunne, McIntosh, & Dunne-Maxim, 1987; Mishara, 1995; National Action Alliance for Suicide Prevention: Suicide Attempt Survivors Task Force, 2014; National Action Alliance for Suicide Prevention: Survivors of Suicide Loss Task Force, 2015). By one conservative estimate, for every death by suicide six people are directly impacted (i.e. survivors). Based on this figure it is estimated that there are over 13 million survivors in the U.S. and unfortunately, survivorship itself is a risk factor for suicide (Crosby & Sacks, 2002). Research indicates that the health consequences of violence, including suicide, are also much more extensive than injury and death. Suicide attempt survivors (i.e. those with lived experience) may suffer long-term health and mental health consequences ranging from anger, guilt, and physical impairment, depending on the means and severity of the attempt (Chapman & Dixon-Gordon, 2007). Similarly, survivors of a loved one's suicide may experience ongoing pain and suffering including complicated grief (Mitchell, Kim, Prigerson, & Mortimer-Stephens, 2004), stigma, depression, anxiety, post-traumatic stress disorder, and increased risk of suicidal ideation and suicide (Julie Cerel, McIntosh, Neimeyer, Maple, & Marshall, 2014; Sudak, Maxim, & Carpenter, 2008).

The economic toll of suicide is immense as well. The total lifetime costs associated with nonfatal injuries and deaths caused by self-directed violence in 2013 were approximately \$93.5 billion after adjusting for under-reporting of suicide (Shepard, Gurewich, Lwin, Reed, & Silverman, 2016). The overwhelming burden of these costs results from lost productivity over the life course, with the average cost per suicide being over \$1.3 million (Shepard et al., 2016).

**Suicide can be prevented.** Despite the myths surrounding suicide, like most public health problems, suicide is preventable (U.S. Public Health Service, 1999). And while progress will continue to be made into the future, evidence for numerous programs, practices, and policies currently exists, and many programs are ready to be implemented now. Just as suicide is not caused by a single factor, research suggests that suicide will not be prevented by any single intervention taking place in any single setting (Silverman & Maris, 1995; U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012). Rather, suicide prevention is best achieved by a focus across the individual-, relationship-, family-, community, and societal-levels and across all sectors, private and public (e.g.,

business, public health, physical and behavioral healthcare, justice, education, labor) (National Action Alliance for Suicide Prevention, 2014; World Health Organization, 2014).

### **Assessing the Evidence**

This technical package includes programs, practices, and policies with evidence of impact on suicide or risk or protective factors for suicide. To be considered for inclusion in the technical package, the program, practice, or policy selected had to meet at least one of these criteria: a) meta-analyses or systematic reviews showing impact on suicide; b) evidence from at least one rigorous (e.g., randomized controlled trial [RCT] or quasi-experimental design) evaluation study that found significant preventive effects on suicide; c) meta-analyses or systematic reviews showing impact on risk or protective factors for suicide, or d) evidence from at least one rigorous (e.g., RCT or quasi-experimental design) evaluation study that found significant impacts on risk or protective factors for suicide. Finally, consideration was also given to the likelihood of achieving beneficial effects on multiple forms of violence; no evidence of harmful effects on specific outcomes or with particular subgroups; and feasibility of implementation in a U.S. context if the program, policy, or practice has been evaluated in another country.

Within this technical package, some approaches do not yet have research evidence demonstrating impact on rates of suicide but instead are supported by evidence indicating impacts on risk or protective factors for suicide (e.g., help-seeking, stigma reduction, depression, connectedness). In terms of the strength of the evidence, programs that have demonstrated effects on suicidal behavior (e.g., reductions in deaths, attempts) provide a higher-level of evidence, but the evidence base is not that strong in all areas. For instance, there has been less evaluation of community engagement and family programs on suicidal behavior. Thus, approaches in this package that have effects on risk or protective factors reflect the developmental nature of the evidence base and the use of the best available evidence at a given time.

It is also important to note that there is often significant heterogeneity among the programs, policies, or practices that fall within one approach or strategy area in terms of the nature and quality of the available evidence. Not all programs, policies, or practices that utilize the same approach (e.g., gatekeeper training) are equally effective, and even those that are effective may not work across all populations. Tailoring programs and more evaluation may be necessary to address different population groups. The examples provided are not intended to be a comprehensive list of evidence-based programs, policies, or practices for each approach, but rather illustrate models that have been shown to impact suicide or have beneficial effects on risk or protective factors for suicide. In practice, the effectiveness of the programs, policies and practices identified in this package will be strongly dependent on the quality of their implementation and the communities in which they are implemented. Implementation guidance to assist practitioners, organizations and communities will be developed separately.

## Context and Cross-Cutting Themes

The strategies and approaches that have been included in this technical package represent different levels of the social ecology, with efforts intended to impact the community and societal levels, as well individual and relationship levels. The strategies and approaches are intended to work in combination and reinforce each other to prevent suicide (see box below). The strategies are arranged in order such that those strategies hypothesized to have the greatest potential for broad public health impact on suicide are included first, followed by those that might impact more select populations (e.g., persons who have already made a suicide attempt).

Preventing Suicide	
Strategy	Approach
Strengthen economic supports	<ul style="list-style-type: none"><li>Strengthen household financial security</li><li>Housing stabilization policies</li></ul>
Strengthen access to mental health care	<ul style="list-style-type: none"><li>Coverage of mental health conditions in health insurance policies</li></ul>
Create protective environments	<ul style="list-style-type: none"><li>Reducing access to lethal means among persons at-risk of suicide</li><li>Organizational policies and culture</li><li>Community-based policies to reduce excessive alcohol use</li></ul>
Promote connectedness	<ul style="list-style-type: none"><li>Peer norm approaches</li><li>Community engagement activities</li></ul>
Teach coping and problem-solving skills	<ul style="list-style-type: none"><li>Social-emotional learning</li><li>Parenting skill and family relationship approaches</li></ul>
Identify and support people at risk	<ul style="list-style-type: none"><li>Gatekeeper training</li><li>Screening combined with care management</li><li>Crisis intervention</li></ul>
Intervene to lessen harms and prevent future risk	<ul style="list-style-type: none"><li>Treatment for people at-risk of suicide</li><li>Treatment to prevent re-attempts</li><li>Postvention</li><li>Safe messaging following a suicide</li></ul>

The example programs, policies, and practices have been implemented within particular contexts. The social and cultural context of communities is critically important to take into account when selecting strategies and approaches. Practitioners in the field may be in the best position to assess the needs and strengths of their communities and work with community members to make decisions about the combination of approaches included here that are best suited to their context.

Suicide ideation, attempts, morbidity and mortality vary by gender, race/ethnicity, age, occupation, and other important population characteristics. Barriers to disclosure, help seeking, timely access to quality care, and ongoing support are profoundly complex and may also vary by population and community characteristics. Ideally, the availability of multiple approaches tailored to the economic, cultural, and environmental context of individuals and communities are desirable as they may increase the likelihood of removing barriers to supportive and effective care and provide opportunities to develop individual and community resilience. These culturally appropriate approaches can then be included in comprehensive strategies to maximize the public health impact on reducing suicide-related morbidity and mortality among individuals and within communities.

This package includes strategies where public health agencies are well positioned to bring leadership and resources to implementation efforts. It also includes strategies where public health can serve as an important collaborator (e.g., strategies addressing community and societal level risks), but where leadership and commitment from other sectors such as business, labor or health care is critical to implement a particular policy or program (e.g., workplace policies; screening combined with care management). The role of various sectors in the implementation of a strategy or approach in preventing suicide is described further in the section on *Sector Involvement*.

In the sections that follow, the strategies and approaches with the best available evidence for preventing suicide are described.

## Strengthen Economic Supports

### Rationale

Studies from the U.S. examining historical trends indicate that suicide rates increase during economic recessions marked by high unemployment rates, job losses, and economic instability and decrease during economic expansions and periods marked by low unemployment rates, particularly for working-age individuals 25 to 64 years old (Luo et al., 2011; Fowler et al., 2015). Economic and financial strain, such as job loss, long periods of unemployment, reduced income, difficulty covering medical, food, and housing expenses, and even the anticipation of such financial stress, increase an individual's risk for suicide; buffering these risks can therefore, potentially protect against suicide (Stack & Wasserman, 2007). For example, strengthening economic support systems can help people pay stay in their homes or obtain affordable housing while also paying for necessities such as food and medical care, job training, child care, among other expenses required for daily living. In providing this support, stress and anxiety and the potential for a crisis situation may be reduced, thereby preventing suicide.

### Approaches

Economic supports for individuals and families can be strengthened by targeting household financial security and ensuring stability in housing during periods of economic stress.

- **Strengthening household financial security** can potentially buffer the risk of suicide by providing individuals with the financial means to lessen the stress and hardship associated with a job loss or other unanticipated financial problems. The provision of unemployment benefits and other forms of temporary assistance, livable wages, medical benefits, and retirement and disability insurance to help cover the cost of necessities or to offset costs in the event of disability, are examples of ways to strengthen household financial security.
- **Housing stabilization policies** aim to keep people in their homes and provide housing options for those in need during times of financial insecurity. This may occur through programs that provide affordable housing such as through government subsidies or through other options available to potential homebuyers such as loan modification programs, move-out planning, or financial counseling services that help minimize the risk or impact of foreclosures and eviction.

### Potential Outcomes

- Reduced suicide rates
- Lower foreclosure rates
- Lower eviction rates
- Reduced emotional distress

## Evidence

There is evidence suggesting that strengthening household financial security and stabilizing housing can reduce suicide risk.

- **Strengthen household financial security.** An examination of variations in U.S. *unemployment benefit programs* across states demonstrated that the impact of unemployment on suicide was offset in those states that provided greater than average unemployment benefits (Cylus, Glymour, & Avendano, 2014). Another U.S. study examining the link between unemployment and suicide risk using monthly suicide data, length of unemployment, and job losses found that the duration of unemployment, as opposed to just the loss of job, predicted suicide risk (Classen & Dunn, 2012). Together, these results suggest that not only should state unemployment benefit programs be generous in their financial allocations, but also in their duration.

Other measures to strengthen household financial security (e.g., transfer payments related to retirement and disability insurance, unemployment insurance compensation, medical benefits, and other forms of family assistance) have also shown an impact on suicide. A study by Flavin and Radcliff (2009) examined the impact of states' per capita spending on transfer payments, medical benefits, and family assistance (Temporary Assistance to Needy Families – TANF) and total state spending on suicide rates between 1990-2000, controlling for a number of suicide risk factors (e.g., residential mobility, divorce rate, unemployment rate) at the state level. As per capita spending on total transfer payments, medical benefits, and family assistance increased there was an associated decrease in state suicide rates. Moreover, it wasn't spending in general that was associated with the reduction but spending on these types of assistance. In terms of lives saved, Flavin & Radcliff calculated the cost of reducing a state's suicide rate by a full point for the years studied. At the national level, they estimated that 3,000 fewer suicides would occur per year nationwide if every state increased their per capita spending on these types of assistance by \$45 per year (Flavin & Radcliff, 2009).

- **Housing stabilization policies.** The *National Neighborhood Stabilization Program* was designed to help neighborhoods suffering from high rates of foreclosure and abandonment by slowing the deterioration of the neighborhoods and providing affordable housing options for low, moderate, and middle-income homebuyers. This program also offers financial assistance to eligible individuals for the purchase of a new home. Although this program has not been rigorously evaluated for its impact on suicide outcomes, it addresses foreclosure and eviction, which are risk factors for suicide. A longitudinal analysis of annual data on suicides and foreclosures demonstrated that as the proportion of foreclosed properties increased in U.S. states, so did the state suicide rate, particularly among working-aged adults (Houle & Light, 2014). Another study of data from 16 U.S. states participating in the National Violent Death Reporting System found

that suicides precipitated by home foreclosures and evictions increased more than 100% from 2005 (before the housing crisis began) to 2010 (after it had peaked; Fowler, Gladden, Vagi, Barnes, and Frazier (2015)). Most of these suicides occurred prior to the actual loss of the decedent's home. These findings suggest that integrating suicide prevention resources, messaging, and referrals into financial, foreclosure, and move-out planning and counseling services may help to prevent suicide.

## Strengthen Access to Mental Health Care

### Rationale

While most people with mental health problems do not attempt or die by suicide (Olfson, Gerhard, Huang, Crystal, & Stroup, 2015; Owens, 2002), and risk conferred by mental illnesses differ (Arsenault-Lapierre, Kim, & Turecki, 2004; E. C. Harris & Barraclough, 1997; Tyrer, Reed, & Crawford, 2015), previous research indicates that mental illness is an important risk factor for suicide (E. C. Harris & Barraclough, 1998; World Health Organization, 2014). Studies suggest that up to 90% of people who die by suicide may have had a mental illness at the time of their deaths (Arsenault-Lapierre et al., 2004; Cavanagh, Carson, Sharpe, & Lawrie, 2003; Isometsa, 2001). State-level suicide rates have also been found to be correlated with general mental health measures such as depression (Lang, 2013; Mark, Shern, Bagalman, & Cao, 2007). Findings from the National Comorbidity Survey indicate that relatively few people in the U.S. with mental health disorders receive treatment for those conditions (Kessler et al., 2005). Lack of access to mental health care is one of the contributing factors related to the underuse of mental health services (Cunningham, 2009). Identifying ways to improve access to timely, affordable, and quality mental health care for people in need is a critical component to suicide prevention (World Health Organization, 2014). Apart from the treatment benefits, it can also serve to normalize help-seeking behavior and increase the use of such services.

### Approaches

One approach to strengthening access to mental health care is through the provision of mental health coverage in health insurance policies.

- **Coverage of mental health conditions in health insurance policies.** Federal and state laws include provisions for equal coverage of mental health services in health insurance plans that is on par with coverage for other health concerns (i.e., mental health parity). Benefits and services covered include such things as the number of visits, co-pays, deductibles, inpatient/outpatient services, prescription drugs, and hospitalizations. If a state has a stronger mental health parity law than the federal parity law, then insurance plans regulated by the state must follow the state parity law. Federal parity replaces the state law only in cases where the state law prevents the application of the federal parity law (e.g., includes coverage for some mental health conditions but not others). Equal coverage does not necessarily imply good coverage as health insurance plans vary in the extent to which benefits and services are offered to address various health conditions. Rather it helps to ensure that mental health services are covered on par with other health concerns.

### Potential Outcomes

- Increased utilization of mental health services

- Decreased symptoms of mental illnesses
- Decreased rates of suicide attempts
- Decreased rates of suicide

## Evidence

There is evidence suggesting that coverage of mental health conditions in health insurance policies can reduce risk factors associated with suicide and may directly impact suicide rates.

- **Coverage of mental health conditions in health insurance policies.** The National Survey of Drug Use and Health is a nationally representative survey of the U.S. population that provides data on substance use, mental health conditions, and services utilization. Using data from this survey, K. M. Harris, Carpenter, and Bao (2006) found that 12 months after states enacted *mental health parity laws*, self-reported use of mental healthcare services significantly increased. Moreover, subsequent research by Lang (2013) examined state mental health laws and suicide rates between 1990 and 2004 and found that mental health parity laws, specifically, were associated with an approximate 5% reduction in suicide rates. This reduction, in the 29 states with parity laws, equated to the prevention of 592 suicides per year and a cost savings of \$1.3-3.1 million per suicide prevented (Lang, 2013).

## Create Protective Environments

### Rationale

Prevention efforts that focus not only on individual behavior change (e.g., help-seeking, treatment interventions) but on changes to the environment can increase the likelihood of positive behavioral and health outcomes (Haddon, 1980). Creating environments that address risk and protective factors where individuals live, work, and play, can help prevent suicide (Dahlberg & Krug, 2002; U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012). For example, rates of suicide and suicide attempts are elevated in certain occupational groups (Han et al., 2016; McIntosh et al., 2016), therefore, changes to the organizational culture in these occupations, by way of implementation of supportive policies or even physical modifications to the workplace environment, can change social norms, encourage help-seeking, and demonstrate that good health and mental health are valued and that stigma and other risk factors for suicide are not (K. L. Knox et al., 2010; National Action Alliance for Suicide Prevention Workplace Task Force, 2015). Similarly, modifying the characteristics of the environment to prevent harmful behavior such as access to lethal means can reduce suicide rates, particularly in times of crisis (Beautrais, Gibb, Fergusson, Horwood, & Larkin, 2009; Crosby, Espitia-Hardeman, Ortega, & Lozano, 2013; Kaplan et al., 2013; Miller, Warren, Hemenway, & Azrael, 2015; C. W. Runyan et al., 2016).

### Approaches

The current evidence suggests three promising approaches for creating environments that protect against suicide.

- **Reducing access to lethal means among persons at-risk of suicide.** Means of suicide such as firearms, hanging/suffocation, or jumping from heights provide little opportunity for rescue and, as such, have high case fatality rates (e.g., about 85% of people who use a firearm in a suicide attempt will die from the injury). Research also indicates that 1) the interval between thinking about and attempting suicide can be as short as 5 or 10 minutes (Deisenhammer et al., 2009; Simon et al., 2001) and 2) that people tend *not* to substitute a different method when a highly lethal method is unavailable or difficult to access (Hawton, 2007; Yip et al., 2012). Therefore, increasing the time interval between the thought and the suicide attempt, for example, by making it more difficult to access lethal means, can be lifesaving. The following are examples of approaches reducing access to lethal means for persons at-risk of suicide:
  - *Intervening at Suicide Hotspots.* Suicide hotspots, or places where suicides may take place relatively easily, include tall structures (e.g., bridges and cliffs), railway tracks, and isolated locations such as parks. Efforts to prevent suicide at these locations include

erecting barriers to prevent jumping and installing signs and telephones to encourage individuals who are considering suicide, to seek help (Cox et al., 2013).

- *Safe Storage Practices.* Safe storage of medications, firearms, and other household products can reduce the risk for suicide by separating individuals who may be vulnerable and/or impulsive from easy access to lethal means. Such practices may include education and counseling around storing firearms--locked in a secure place (e.g., in a gun safe or lock box), unloaded and separate from the ammunition--and keeping medicines in a locked cabinet or other secure location away from people who may be at risk or who have made prior attempts (Rowhani-Rahbar, Simonetti, & Rivara, 2016; C. W. Runyan et al., 2016).
- **Organizational policies and culture** that promote protective environments may be implemented in places of employment. Such policies and cultural values may promote prosocial behavior (e.g., asking for help), skill building, changing social norms, referral and access to helping services (e.g. mental health, substance abuse treatment, financial counseling), and encourage leadership support from the top down. Such policies and cultural shifts can positively impact organizational climate and morale and help prevent suicide and its related risk factors (e.g. depression, social isolation) (National Action Alliance for Suicide Prevention Workplace Task Force, 2015).
- **Community-based policies to reduce excessive alcohol use.** Research studies in the United States have found that greater alcohol availability is positively associated with alcohol-involved suicides (Escobedo & Ortiz, 2002; Giesbrecht et al., 2015). Policies to reduce excessive alcohol use broadly include zoning to limit alcohol outlet locations and density, taxes on alcohol, and bans on the sale of alcohol for individuals under the legal drinking age. These policies are important because acute alcohol use has been found to be associated with more than one-third of suicides and approximately 40% of suicide attempts (Cherpitel, Borges, & Wilcox, 2004).

### Potential Outcomes

- Increase in safe storage of means
- Reduction in suicide attempts
- Reduction in suicide deaths
- Increase in help-seeking
- Reduction in alcohol-related suicide deaths

### Evidence

The evidence for the effectiveness reducing access to lethal means for person at-risk of suicide and other ways to establish protective environments is some of the strongest in the field (Zalsman et al., 2016).

- **Reducing access to lethal means among persons at-risk of suicide.** A meta-analysis examining the impact of *suicide hotspot interventions* implemented in combination or in isolation, both in the U.S. and abroad, found associated reduced rates of suicide (Cox et al., 2013; Pirkis et al., 2015). For example, after erecting a barrier on the Jacques-Cartier bridge in Canada, the suicide rate from jumping from the bridge decreased from about 10 suicide deaths per year to about 3 deaths per year (Perron, Burrows, Fournier, Perron, & Ouellet, 2013). Moreover, the reduction in suicides by jumping was sustained even when all bridges and nearby jumping sites were considered, suggesting little to no displacement of suicides to other jumping sites (Perron et al., 2013). Further evidence for the effectiveness of bridge barriers was demonstrated by a study examining the impact of the *removal* of safety barriers from the Grafton Bridge in Auckland, New Zealand. After removal of the barrier, sadly, both the number and rate of suicide increased fivefold (Beautrais, 2001; Beautrais et al., 2009).

Another form of means reduction involves implementation of *safe storage practices*. In a case-control study of firearm-related events identified from 37 counties in Washington, Oregon, and Missouri, and from 5 trauma centers, Grossman et al. (2005) found that storing firearms unloaded, separate from ammunition, in a locked place and/or secured with a safety device was protective of suicide attempts among adolescents. Further, a recent systematic review of clinic and community-based education and counseling interventions suggested that the provision of safety devices significantly increased safe firearm storage practices compared to counseling alone or compared to the provision of economic incentives to acquire safety devices on one's own (Rowhani-Rahbar et al., 2016).

Another program, *The Emergency Department Counseling on Access to Lethal Means (ED CALM)*, trained psychiatric emergency clinicians in a large children's hospital to provide lethal means counseling and safe storage boxes to parents of patients under age 18 receiving care for suicidal behavior. In a pre-post quality improvement project, Runyan et al (2016) found that at post-test 76% (of the 55% of parents followed up, n=114) reported that all medications in the home were locked up as compared to fewer than 10% at the time of the initial emergency department visit. Among parents who indicated the presence of guns in the home at pre-test (i.e. 67%), all (100%) reported guns were currently locked up at post-test (C. W. Runyan et al., 2016).

- **Organizational policies and culture.** *Together for Life* is a workplace program of the Montreal Police Force implemented to address suicide among officers. Policy and program components were designed to foster an organizational culture that promoted mutual support and solidarity among all members of the Force. The program included training of supervisors, managers and all units to improve competencies in identifying suicidal risk and to improve use and awareness of existing resources. The program also included an education campaign to improve awareness and help-seeking (Mishara & Martin, 2012). Police suicides were tracked over 12 years and

compared to rates in the control city of Quebec. The suicide rate in the intervention group decreased significantly by 78.9% to a rate of 6.42 suicides per 100,000 population per year compared to an 11% increase in the control city (rate: 29.0 per 100,000) (Mishara & Martin, 2012).

Another example of this approach is the *United States Air Force Suicide Prevention Program (AFSPP)*. AFSPP included 11 policy and education initiatives and was designed to change the culture of the Air Force surrounding suicide. The program uses leaders as role models and agents of change, establishes expectations for behavior related to awareness of suicide risk, develops population skills and knowledge (i.e., education and training), and investigates every suicide (i.e., outcomes measurement). The program represents a fundamental shift from viewing suicide and mental illness solely as medical problem and instead sees them as larger service-wide problems impacting the whole community (K. L. Knox, Litts, Talcott, Feig, & Caine, 2003). Using a time-series design to examine the impact of the AFSPP program on various violence-related outcomes, researchers found that the program was associated with a 33% relative risk reduction in suicide (K. L. Knox et al., 2003). The program was also associated with relative risk reductions in related outcomes including moderate and severe family violence (30% and 54%, respectively), homicide (51%), and accidental death (18%) (K. L. Knox et al., 2003). A longitudinal assessment of the program over the period 1981 to 2008 (16 years before the 1997 launch of the program and 11 years post-launch) found significantly lower rates of suicide after the program was launched than before (K. L. Knox et al., 2010). These effects were sustained over time, except in 2004, which the authors found was associated with less rigorous implementation in that year than in the other years (K. L. Knox et al., 2010).

- **Community-based policies to reduce excessive alcohol use.** While multiple policies to limit alcohol use exist, several studies on alcohol outlet *density*, specifically, suggest that measures to reduce alcohol outlet density can potentially reduce alcohol-involved suicides. Additionally, a longitudinal analysis of alcohol outlet density, suicide mortality, and hospitalizations for suicide attempts over 6 years in 581 California zip codes indicated that the density of bars, specifically, is related to suicide and suicide attempts, particularly in rural areas (Johnson, Gruenewald, & Remer, 2009).

## Promote Connectedness

### Rationale

Sociologist, Emile Durkheim theorized in 1897 that weak social bonds, i.e. lack of connectedness, are among the chief causes for suicidality (Durkheim, 1897/1951). *Connectedness* is the degree to which an individual or group of individuals are socially close, interrelated, or share resources with others (Centers for Disease Control and Prevention, 2009). Social connections can be formed within and between multiple levels of the social ecology (Dahlberg & Krug, 2002), for instance between individuals (e.g. peers, neighbors, co-workers), families, schools, neighborhoods, workplace, faith communities, cultural groups, and society as a whole. Related to connectedness, *social capital* refers to a sense of trust in one's community and neighborhood, social integration, and also the availability and participation in social organizations (Beyer, Layde, Hamberger, & Laud, 2015; Muennig, Cohen, Palmer, & Zhu, 2013). Many ecological cross-sectional and longitudinal studies have examined the impact of aspects of social capital on depression symptoms, depressive disorder, mental health more generally, and suicide. While the evidence is still being built the pattern is towards an inverse association between social capital measured by social trust, community/ neighborhood engagement, and improved mental health. Connectedness and social capital together can serve to protect against suicidal behaviors by decreasing isolation, encouraging adaptive coping behaviors, increasing belongingness, personal value and worth all of which helps individuals to build resilience in the face of adversity. Connectedness can also provide individuals with better access to formal supports and resources, mobilize communities to meet the needs of its members and provide collective primary prevention activities to the community as a whole (Centers for Disease Control and Prevention, 2009).

### Approaches

Promoting connectedness among individuals and within communities through modeling peer norms and enhancing community engagement can protect against suicide.

- **Peer norm approaches** seek to normalize prosocial behaviors/protective factors for suicide such as help-seeking, reaching out and talking to trusted adults, and peer connectedness. These approaches typically target youth and are delivered in school settings but can also be implemented in community settings.

- **Community engagement activities.** Community engagement is an aspect of social capital. Community engagement approaches may involve residents participating in a range of activities, including religious activities, community clean-up and greening activities, and physical exercise. These activities provide opportunities for residents to become more involved in the community and to connect with other community members, organizations, and resources, resulting in enhanced overall physical health, reduced stress, and decreased depressive symptoms, thereby reducing risk of suicide.

### Potential Outcomes

- Reduction in maladaptive coping attitudes and behaviors
- Increase in healthy coping attitudes and behaviors
- Increase in referrals for youth in distressed
- Increase help-seeking behaviors
- Positive perception of adult support

### Evidence

Current evidence suggests that peer norm approaches and community engagement can reduce risk factors associated with suicidal behaviors.

- **Peer norm approaches.** Evaluations show that programs such as *Sources of Strength* can improve school norms and beliefs about suicide that are created and disseminated by student peers. In a randomized controlled trial of *Sources of Strength* conducted with 18 high-schools (6 metropolitan, 12 rural), Wyman et al. (2010) found that the program improved peer leaders' adaptive norms regarding suicide, their connectedness to adults, and school engagement. Peer leaders were also more likely than controls to refer a suicidal friend to an adult. Among students, the intervention increased perceptions of adult support for suicidal youths and the acceptability of seeking help. Perception of adult support increased most in students with a history of suicidal ideation. Finally, trained peer leaders also reported a greater decrease in maladaptive coping attitudes compared with untrained leaders (Wyman et al., 2010).
- **Community engagement activities.** A vacant lot greening initiative was undertaken in Philadelphia between 1999 and 2008. Local residents and community members worked together to green 4,436 lots (or 7.8 million square feet) in 4 areas of the city. Researchers found significant associated reductions in community residents' self-reported stress levels and engagement in more physical exercise than residents in control vacant lot areas. Other benefits included reductions in firearm assaults and vandalism (Branas et al., 2011).

## Teach Coping and Problem-Solving Skills

### Rationale

Building life skills prepares individuals to successfully tackle every day challenges and adapt to stress and adversity. Life skills encompasses many concepts, but most often include coping and problem-solving skills, conflict resolution, and critical thinking. Life skills are important in shielding individuals from suicidal behaviors (World Health Organization, 2014). Suicide prevention programs that focus on life and social skills training are drawn from social cognitive theories (Bandura, 1986), surmising that individuals who engage in suicidal behavior is attributed to either direct learning, modeling, and environmental and individual (e.g. hopelessness) characteristics. The literature linking life skills and suicide is robust--- The inability to employ adequate coping strategies to cope with immediate stressors or identify and find solutions for problems have been characterized among suicide attempters (Pollock & Williams, 2004). Treatments that include bolstering problem skills (Goldsmith, Pellmar, Kleinman, & Bunney, 2002) and include problem-solving techniques (Ghahramanlou-Holloway, Bhar, Brown, Olsen, & Beck, 2012; Townsend et al., 2001) appear to reduce suicidal ideation and attempts more effectively. Prevention programs focused on teaching these skills target youth, parents and families and have been used with both universal and at-risk populations. While many do not target suicidal behaviors directly, these programs strive to train youth and parents important life skills to offset the underlying vulnerabilities that contribute to engaging in high risk behaviors early in life.

### Approaches

Current evidence provides support for the following two approaches:

- **Social emotional learning programs** focus on developing and strengthening communication and problem-solving skills, emotion regulation, conflict resolution, help seeking and coping skills. These approaches address a range of risk and protective factors for suicidal behavior. They provide children and youth with skills to resolve problems in relationships, school, and with peers, and help youth to address other negative influences (e.g., substance use) associated with suicide. These approaches are typically delivered to all students in a particular grade or school, although some programs also focus on groups of students considered to be at high-risk for suicide. Opportunities to practice and reinforce skills are an important part of programs that work (Herman, Borden, Reinke, & Webster-Stratton, 2011).
- **Parenting skill and family relationship programs** are designed to strengthen parenting skills, enhance positive parent-child interactions, and improve children's behavioral and emotional skills and abilities. Several parenting and family relationship programs have been shown in rigorous evaluations to improve resilience and reduce risk factors for various behaviors, including

ones closely related to suicide, such as depression, internalizing behaviors, and substance abuse (M. S. Knox, Burkhart, & Hunter, 2010).

### Potential Outcomes

- Reduction in suicide attempts and suicide ideation
- Enhanced knowledge of risk and protective factors associated with suicide
- Reduction in suicide risk behaviors (i.e., depression, anxiety, conduct problems, substance abuse)
- Improve and normalize help-seeking behavior
- Enhance social competence and emotional regulation skills
- Enhance problem-solving and conflict management skills

### Evidence

There are several programs with evidence that support teaching social, emotional and parenting skills to reduce suicidal behaviors and associated risk factors.

- **Social emotional learning programs.** The *Youth Aware of Mental Health Program (YAM)* is a program developed for teenagers that uses interactive dialogue and role-playing to teach adolescents about the risk and protective factors associated with suicide (including knowledge about depression and anxiety) and enhances their problem-solving skills for dealing with adverse life events, stress, school and other problems. The program includes 3 hours of role-play sessions and interactive workshops combined with a booklet that students can keep, educational posters displayed in classroom, and interactive lectures about mental health at the beginning and end of the program (Wasserman et al., 2014). In a cluster-randomized controlled trial of YAM conducted across 10 European Union countries and 168 schools, students participating in the YAM program were significantly less likely to have an incident suicide attempt (OR 0.45, 95%CI 0.24–0.85;  $p=0.014$ ) and severe suicidal ideation (0.50, 0.27-0.92;  $p=0.025$ ) at the 12-month follow-up compared to the control group. Additionally, related to severe suicide ideation, in the YAM group absolute risk fell by 0.50% and RR fell by 49.6% (Wasserman et al., 2014).

*Signs of Suicide (SOS)* is another school-based prevention program for students aged 13-17. The program includes guided classroom discussions about suicide and depression. As part of the program, students are screened for depression and suicide risk and referred for professional help as indicated. The program is designed to increase knowledge about suicide and risk factors associated with suicidal behavior as well as improve and normalize help-seeking behavior (Schilling, Aseltine, & James, 2016). In a randomized controlled trial, SOS was shown to reduce self-reported suicide attempts at 3-months post intervention among

participating students compared to control students. The SOS program also increased students' knowledge of how to get help for themselves or friends for depression and/or suicidal thoughts, and favorable attitudes toward help-seeking. SOS participants with a lifetime history of suicide attempt were also less likely to report planning a suicide in the 3 months following the program compared to lower-risk participants (Schilling et al., 2016).

Finally, the *Good Behavior Game (GBG)* is a classroom-based program for elementary school children aged 6-10; it represents an example of upstream suicide prevention programming. The program uses a team-based behavior management strategy that promotes good behavior by setting clear expectations for good behavior and consequences for maladaptive behavior. The goal of the GBG is to create an integrated classroom social system that is supportive of all children being able to learn with little aggressive or disruptive behavior (Wilcox et al., 2008). In an outcome evaluation of the GBG, first graders assigned to GBG reported half the adjusted odds of suicidal ideation and suicide attempts. The beneficial effect of the program was consistent for suicidal ideation regardless of whether baseline covariates were included. The GBG effect on attempts was less robust in some adjusted models including caregiver mental health. In the second cohort of GBG students, neither suicidal ideation nor suicide attempts were significantly different between GBG and the control interventions (Wilcox et al., 2008). This finding likely arose due to the lack of implementation fidelity and pointed to the need for GBG to be delivered with precision, consistency, and teacher support. GBG was also found to be associated with reduced risk of later substance abuse, a risk factor for suicide (Kellam et al., 2008).

- **Parenting skill and family relationship programs.** Parenting and family skills training approaches have shown promising impacts in preventing key risk factors associated with suicide. For example, the *Incredible Years (IY)* is a comprehensive group training program for parents, teachers and children designed to reduce conduct and substance abuse problems, two important suicide risk factors, in youth by improving protective factors such as responsive and positive parent-teacher-child interactions and relationships, emotion self-regulation and social competence (all protective factors for suicide) (Herman et al., 2011). The program includes 9- 20 sessions offered in community-based settings (e.g., religious, recreation centers, mental health treatment centers, and hospitals). Several studies have demonstrated the effect of the IY program on reducing internalizing symptoms, such as anxiety and depression, and child conduct problems (C. H. Webster-Stratton, Reid, & Beauchaine, 2011; Webster-Stratton, Jamila Reid, & Stoolmiller, 2008). The program is also associated with improved problem-solving and conflict management; these skills were maintained at 1-year follow-up (Reid, Webster-Stratton, & Hammond, 2003; C. Webster-Stratton & Hammond,

1997; C. Webster-Stratton, Reid, & Hammond, 2001). The program demonstrated greater benefits as the dosage of the intervention increased (Herman et al., 2011).

Additionally, *Strengthening Families 10-14* is a program that involves sessions between parents, youth, and family with the goal of improving parents' skills for disciplining, managing emotions and conflict, and communicating with their children; promoting youths' interpersonal and problem-solving skills; and creating family activities to build cohesion and positive parent-child interactions. The premise of the program is that developing these skills for both parents and children will reduce internalizing behavior and adolescent substance abuse, two important risk factors for suicide (Spoth, Gyll, & Day, 2002). *Strengthening Families* has been shown to decrease externalizing behaviors, alcohol use, and drug use among youth participants and reductions in depression, alcohol use, and drug use among participating families (Spoth et al., 2002).

## Identify and Support People At-Risk

### Rationale

In order to decrease suicide, attention to people at increased or high risk is necessary as these individuals tend to experience suicidal behavior at higher than average rates. These vulnerable or disadvantaged populations include, but are not limited to, individuals with lower socio-economic status or who are living with a mental health problem; people who have attempted suicide previously, individuals who are institutionalized, have been victims of violence, or are homeless; and members of certain ethnic minority groups. Supporting these vulnerable groups requires proactive case finding along with access to, and retention in, mental health services. Finding effective ways of identifying at-risk or vulnerable groups, customizing services to make them accessible and maintaining care remain key challenges. For example, simply improving services does not guarantee that those services will be used by those most in need of them, nor will it necessarily increase the number of people who follow treatments that are recommended. People who are disadvantaged face social and economic issues that may adversely affect their ability to respond to the treatments or advice that are offered.

### Approaches

The following three approaches focus on identifying and supporting people at increased risk.

- **Gatekeeper training** is designed to train teachers, coaches, providers and others in the community to identify people who may be at risk of suicide and to respond effectively, including facilitating treatment seeking and support services. Gatekeeper training is typically implemented in schools to identify at-risk youth and within health care settings to identify adults (and youth).
- **Screening combined with care management and overall continuity of care** has been used in primary care and behavioral health care settings to assure that people who may be at high-risk of suicide are identified and receive ongoing treatment as needed, particularly after inpatient discharge and other transitions within the healthcare system so they don't 'slip through the cracks'. These approaches typically employ screening for depression and/or suicide combined with collaborative treatment planning between patients and their providers and patient follow-up.
- **Crisis intervention.** These approaches provide support and referral services, typically by connecting a person in crisis (or a friend or family member of someone at-risk) to trained volunteers and/or professional staff via telephone hotline, online chat, or text messaging. Crisis intervention approaches are intended to impact key risk factors for suicide, including feelings of depression, hopelessness, and subsequent mental health care utilization. Like means reduction,

crisis interventions can put space or time between an individual who may be considering suicide and harmful behavior.

### Potential Outcomes

- Reduction in suicide attempts
- Reduction in suicide deaths
- Increased identification of individuals at-risk for suicidal behavior
- Increased at-risk individuals in treatment
- Increased community members trained to identify at-risk individuals
- Increased referrals for health care

### Evidence

There is evidence that community gatekeeper programs are successful in reducing suicides and suicide attempts but the efforts must be maintained (Substance Abuse and Mental Health Services Administration, 2014). However, there is limited evidence for effectiveness screening programs, but at the same time, standard principles for public health screening make them promising (Pena & Caine, 2006). The number of studies evaluating crisis intervention services is limited, but a few studies do indicate that those who use the hotline services have decreased suicidal thoughts and behavior.

- **Gatekeeper training.** One example of gatekeeper training is the *Mental Health First Aid (MHFA)* program. This program is designed for the lay public and consists of three weekly sessions of three hours each. Participants learn the symptoms of people in mental health crises and/or in the early stages of mental health problems (i.e., those experiencing suicidal thoughts and behavior, acute stress reaction, panic attacks and acute psychotic behavior, and depression, anxiety, and psychotic disorders), possible risk factors, and where and how to get evidence-based effective help (Kitchener & Jorm, 2004). In a randomized controlled trial of 300 participants of *MHFA*, the intervention group reported greater confidence in providing help to others, greater likelihood of advising people to seek professional help, improved concordance with health professionals about treatments, and decreased stigmatizing attitudes. Additionally, the intervention resulted in improved mental health of the participants themselves. All results were statistically significant at  $p < .05$ . (Kitchener & Jorm, 2004). Additional research rigorously evaluating *MHFA* for its impact on the first aid recipients themselves and suicidal behavior is needed (Kitchener & Jorm, 2006).

Gatekeeper training has also been a core part of all *Garret Lee Smith (GLS) Suicide Prevention Program* which is in place in 49 states and 48 tribes. A multi-site evaluation assessed the

connection between community gatekeeper training and a reduction of suicide attempts and deaths by comparing the change in suicide mortality rates and nonfatal suicidal behavior among the population aged 10-24 in counties implementing *GLS* trainings, with the trajectory observed in similar counties that did not implement these trainings. Counties implementing *GLS* trainings had significantly lower youth suicide rates the year following the training implementation (-1.07,  $p=.03$ ) (Walrath, Garraza, Reid, Goldston, & McKeon, 2015). This finding represents a decrease of 1 suicide death per 100,000 10 to 24 year olds or the avoidance of approximately 237 deaths in this age group between 2007 and 2010. Counties implementing *GLS* program activities also had significantly lower suicide attempt rates among youths 16 to 23 years of age in the year following implementation of the *GLS* program than did similar counties that did not implement *GLS* program activities (4.9 fewer attempts per 1000 youths [95% CI, 1.8-8.0 fewer attempts per 1000 youths];  $p = .003$ ; (Godoy Garraza, Walrath, Goldston, Reid, & McKeon, 2015)). More than 79 000 suicide attempts may have been averted during the period studied following implementation of the *GLS* program.

- **Screening combined with care management and overall continuity of care.** The *Henry Ford Perfect Depression Care* program was the pre-cursor to *Zero Suicide*, and its overall goal was to eliminate suicide. More broadly, though, the aim was to completely redesign depression care delivery to achieve breakthrough improvement in quality and safety by focusing on six aims: effectiveness, safety, patient centeredness, timeliness, efficiency, and equity among patients. The program developed concrete measures to assess progress on each of these aims and began with screening and assessment of each patient for suicide risk with coordinated continuous follow-up care system wide (C. E. Coffey, 2006). An examination of the impact of the *Henry Ford Perfect Depression Care (Pre-cursor to Zero Suicide)* program found that there was a dramatic and statistically significant decrease in the rate of suicide between the baseline years prior to the intervention (1999 and 2000) to the intervention years (2002-2009). During this time period, the suicide rate fell 82% (C. E. Coffey, 2006; C. E. Coffey, Coffey, & Ahmedani, 2013). Further, suicide rates also declined among HMO members who participated in targeted suicide prevention efforts and received mental health specialty services. However, for those HMO members who accessed only general medical services as opposed to specialty mental health services, the suicide rate increased (M. Coffey, Coffey, & Ahmedani, 2015).
- **Crisis intervention.** Suicide prevention hotlines are one way to provide crisis intervention. In an evaluation of the effectiveness of the *National Suicide Prevention Lifeline (NSPL)* to prevent suicide, 1,085 suicidal individuals who called the hotline completed a standard risk assessment for suicide, and 380 of those completed a follow-up assessment between 1 and 52 days after the initial assessment. Researchers found that over half of the initial sample were seriously considering suicide when they called, and they had a plan for their suicide. Researchers also

found that participants experienced significant decreases in suicidality over the course of the telephone session, and that levels of hopelessness and psychological pain continued to decrease after their initial call (Gould, Kalafat, Harrismunfakh, & Kleinman, 2007).

In another study, this time employing a randomized controlled trial, Gould, Cross, Pisani, Munfakh, and Kleinman (2013) assessed the impact of the *Applied Suicide Intervention Skills Training (ASIST)*, a widely implemented training program that helps hotline counselors, emergency workers, and other gatekeepers to identify and connect with suicidal individuals, understand their reasoning for living and dying, and assist with safely connecting those in need to available resources. The training was evaluated across the NSPL network of hotlines over the period 2008-2009. Using data from 1,410 suicidal individuals who called 17 Lifeline centers, researchers found that compared to callers who spoke to counselors that received the usual care training, individuals who spoke with counselors trained in *ASIST* were significantly more likely to feel less depressed, less suicidal, less overwhelmed, and more hopeful by the end of their call to the hotline. Counselors trained in *ASIST* were also more skilled at keeping callers on the phone longer and establishing a connection with them. However, training in *ASIST* did not result in more comprehensive suicide risk assessments than usual care training (Gould et al., 2013).

## Intervene to Lessen Harms and Prevent Future Risk

### Rationale

Individuals who have experienced mental health challenges, suicidal ideation, and/or who have made suicide attempts and/or have engaged in non-suicidal self-injury are at increased risk of suicide (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012). Risk of suicide can also increase among those who have lost a friend, family member, co-worker, or other acquaintance to suicide (Pitman, Osborn, King, & Erlangsen, 2014). Exposure to sensationalized or uninformed reporting regarding on suicide may heighten the risk of suicide among vulnerable individuals and can inadvertently contribute to suicide contagion (Etzersdorfer & Sonneck, 1998; Niederkrotenthaler & Sonneck, 2007).

### Approaches

A broad array of approaches to lesson harms and reduce future risk of suicide among those at increased risk include the provision of mental health care and improved continuity of care, improving linkage to care through active post-discharge planning and follow-up that decreases barriers to ongoing therapeutic support, increasing connectedness to supportive others, addressing bereavement, and framing communications to emphasize resilience, decrease negative affect, and to prevent contagion.

- **Treatment for people at-risk of suicide** typically includes various forms of psychotherapy delivered by licensed providers to help individuals with mental health problems and other risk factors for suicide with problem-solving, impulsivity and emotion regulation.
- **Treatment to prevent re-attempts.** These approaches typically include follow-up contact and use diverse modalities (e.g., home visits, mail, telephone, e-mail) to engage recent suicide attempt survivors in continued treatment to prevent re-attempts. Treatment may focus on improved coping skills, mindfulness, and other emotional regulation skills, and may include case management home visits to increase adherence to treatment and continuity of care; and one-on-one interpersonal therapy and/or group therapy. Approaches that engage and connect attempters to peers and providers are especially important because many attempters do not present to aftercare; 12%-25% reattempt within a year, and 3%-9% of attempt survivors die by suicide within 1 to 5 years of their initial attempt (Inagaki et al., 2015)
- **Postvention** approaches are implemented *after* a suicide has taken place and may include debriefing sessions, counseling, and/or bereavement support groups for surviving friends and family members/loved ones. These programs have not typically been evaluated for their impact on suicide or suicidal behavior but may reduce survivors' guilt, feelings of depression, and complicated grief (Szumilas & Kutcher, 2011).

- **Safe messaging following a suicide.** The manner in which information on a recent suicide is communicated to the public (e.g. school assemblies, mass media, social media) can heighten the risk of suicide among vulnerable individuals and can inadvertently contribute to suicide contagion. Therefore, responsible and safe reporting may help prevent suicide and/or suicide contagion.

### Potential Outcomes

- Reduction in mental health-related sequelae
- Increase connectedness
- Improved coping skills
- Improved messaging following suicide
- Reduction in re-attempts

### Evidence

The evidence addressing strategies to lesson harm and prevent future risk of suicide includes the evaluation of effects of specific approaches on risk and protective factors as well as suicide-related mortality. However, because the evaluation of suicide-related mortality requires large sample sizes and extended follow-up, much of the evidence in this area primarily focuses on risk and protective factors.

- **Treatment for people at-risk of suicide.** There are a number of treatments with evidence of impact on risk and protective factors for suicide. One example is the *Improving Mood – Promoting Access to Collaborative Treatment (IMPACT)* program. *IMPACT* aims to prevent suicide among older primary care patients by reducing suicide ideation and depression in primary care settings. It facilitates the development of a therapeutic alliance, a personalized treatment plan that includes patient preferences, as well as proactive follow-up (biweekly during an acute phase and monthly during continuation phase) by a depression care manager (Hunkeler et al., 2006). The program has been shown to significantly improve quality of life, and to reduce functional impairment, depression and suicidal ideation over 24-months of follow-up (Hunkeler et al., 2006; Unutzer et al., 2006) relative to patients who received care as usual.

Another example is *Collaborative Assessment and Management of Suicidality (CAMS)*, which is a therapeutic approach for suicide-specific assessment and treatment of patient's suicide risk. This flexible approach can be used across treatment settings and clinician theoretical orientations and involves the clinician and patient working together in an interactive assessment process to develop patient-specific treatment plans. *CAMS* sessions are collaborative and involve constant

patient about what is and is not working with the ultimate goal of enhancing the therapeutic alliance and increasing treatment motivation in the suicidal patient. CAMS been tested and supported in 6 correlational studies (Jobes, 2012), in a variety of inpatient and outpatient settings and in one RCT with several additional RCTs under way. CAMS has been associated with significant improvements in suicidal ideation, overall symptom distress, and feelings of hopelessness at 12 month follow-up among a community-based sample of suicidal outpatients. (Comtois et al., 2011).

Other examples include *Dialectical Behavioral Therapy (DBT)* and *Attachment-Based Family Therapy (ABFT)*. DBT is a multicomponent therapy for individuals at high risk for suicide and who may struggle with impulsivity and emotional regulation. The components of DBT include individual therapy, group skills training, between-session telephone coaching and a therapist consultation team. In a randomized controlled trial of women with recent suicidal or self-injurious behavior, those receiving DBT were half as likely to make a suicide attempt at two-year follow-up than women receiving community treatment (23% vs 46%), required less hospitalization for suicide ideation, and had lower medical risk across all suicide attempts and self-injurious acts combined (Linehan et al., 2006).

ABFT is a program for adolescents aged 12-18 and is designed to treat clinically diagnosed major depressive disorder, eliminate suicidal ideation, and reduce dispositional anxiety (Diamond et al., 2010). A randomized controlled trial of ABFT found that suicidal adolescents assigned to ABFT experienced significantly greater improvement in suicidal ideation over 24 weeks of follow-up than did adolescents assigned to enhanced usual care (-4.37 vs. -2.34;  $p = .001$ ;  $d=0.97$ ). Additionally, a higher percentage of ABFT participants reported no suicidal ideation in the week prior to assessment at 12 weeks than did adolescents receiving enhanced usual care (69.2% vs. 34.6%;  $p = .01$ ; OR= 4.25) and at 24 weeks (82.1% vs. 46.2%;  $p = .006$ ; OR=5.37) (Diamond et al., 2010).

- **Treatment to prevent re-attempts.** Several strategies that aim to prevent re-attempts have demonstrated impact on reducing suicidal behavior. For example, *Emergency Department Brief Intervention with Follow-up Visits* is a program that involves a one-hour discharge information session that addresses suicidal behavior, distress, risk and protective factors, alternatives to suicidal behavior, and referral options, combined with nine follow-up contacts over 18-months (at 1, 2, 4, 7, 11 weeks and 4, 6, 12, 18 months). Follow-up contacts are either conducted by phone or through home visits according to a specific time line for up to 18-months. A randomized controlled trial that enrolled suicide attempters from eight hospital emergency departments in five culturally different sites found that a brief intervention combined with 9 follow-up visits over 18-months was associated with significantly fewer deaths from suicide relative to a treatment-

as-usual group (0.2% versus 2.2%, respectively;  $\chi^2 = 13.83$ ,  $P < 0.001$ ) (Fleischmann et al., 2008).

Another example of treatment to prevent re-attempts involves *active follow-up contact approaches* such as postcards, letters, and telephone calls, are intended to increase a patient's sense of connectedness with health care providers and decrease isolation. These approaches include expression of care and support and typically invite patients to reconnect with their provider. Contacts are made periodically (e.g., monthly or every few months in the first 12 months post-discharge with some programs continuing contact for 2 or more years). These approaches have been found in a meta-analysis conducted by Inagaki et al. (2015) to reduce reattempts by approximately 17% for up to 12 months post-discharge, however, the long-term effects of these approaches on reattempts has not yet been demonstrated. Also, because the number of trials and associated sample sizes included in this meta-analysis were small, it was not possible to determine the effect of active contact and follow-up approaches on death by suicide.

In a randomized controlled trial of post-crisis suicide prevention long-term follow-up contact approach, Motto and Bostrom (2001) found that patients who refused ongoing care but who were randomized to be contacted by letter four times per year had a lower rate of suicide over two years of follow-up than did patients in the control group who received no further contact. Other studies have also shown post-crisis letters and coping cards to be protective against suicide ideation and attempts (Hassanian-Moghaddam, Sarjami, Kolahi, & Carter, 2011; Wang et al., 2016).

Finally, *Cognitive Behavior Therapy for Suicide Prevention (CBT-SP)* is an example of a therapeutic approach to prevent re-attempts. It uses a risk reduction, relapse prevention approach that includes an analysis of proximal risk factors and stressors (e.g., relationship problems, school or work-related difficulties) leading up to and following the suicidal event; safety plan development; skill building; and psychoeducation. *CBT-SP* also has family skill modules focused on family support and communication patterns as well as improving the family's problem solving skills. A randomized controlled trial found of *CBT-SP* found that 10-session outpatient cognitive therapy designed to prevent repeat suicide attempts resulted in a 50% reduction in the likelihood of a suicide reattempt among adults who had been admitted to an emergency department for a suicide attempt relative to treatment as usual (Brown et al., 2005).

- **Postvention** programs are implemented with the goal of providing support to survivors of suicide to reduce their own risk of suicide. One example of a postvention program, *StandBy Response Service (StandBy)*, provides clients with face-to-face outreach and telephone support through a professional crisis response team. Site coordinators develop customized case management plans, referring clients to other existing community services matched to their needs (Visser, Comans, &

Scuffham, 2014). In a study by Visser et al. (2014), *StandBy* clients were significantly less likely to be at high risk for suicidality than a suicide bereaved comparison group who had not had contact with the *StandBy* program (48% and 64% respectively,  $p = 0.005$ ). Additionally, research suggests that active postvention approaches in which outreach to suicide survivors occurs at the scene of a suicide is associated with intake into treatment sooner, greater attendance at support group meetings, and attendance at more meetings compared to passive postvention (versus passive approaches where survivors self-refer for services) (J. Cerel & Campbell, 2008).

- **Safe messaging following a suicide.** Safe messaging after a suicide can help assure that reporting of the event is done in such a way to reduce risk to consumers of news media and other messaging who may be particularly vulnerable. One way to ensure safe messaging following a suicide is to encourage that reporters adhere to *media guidelines for reporting on suicides*. Reports that are both inclusive of suicide prevention messages, stories of hope and resilience, risk and protective factors, and links to helping resources (e.g., hotline) and that avoid sensationalizing events or reducing suicide to one cause can help reduce the likelihood of suicide contagion. The most compelling evidence supporting the effect of *media guidelines* on reduction in suicides comes from Austria. After a sharp increase in suicides on the Viennese subway, media guidelines were introduced and an interrupted time series design was used to evaluate the national impact of the guidelines on subsequent suicides. Changes in the quality and quantity of media reporting resulted in a reduction of 81 suicides annually (95% confidence interval: -149 to -13;  $t = -2.32$ ,  $df = 54$ ,  $p < 0.024$ ) in the Viennese subway system (Niederkrotenthaler & Sonneck, 2007)

## Sector Involvement

Public health can play an important and unique role in addressing suicide. Public health agencies, which typically place prevention at the forefront of efforts and work to create broad population-level impact, can bring critical leadership and resources to bear on this problem. For example, these agencies can serve as a convener, bringing together partners and stakeholders to plan, prioritize, and coordinate suicide prevention efforts. Public health agencies are also well positioned to collect and disseminate data, implement preventive measures, evaluate programs, and track progress. Although public health can play a leadership role in preventing suicide, the strategies and approaches outlined in this technical package cannot be accomplished by the public health sector alone. As noted in the National Strategy to Prevent Suicide, the integration and coordination of prevention activities across sectors and settings is critical for expanding the reach and impact of suicide prevention efforts.

Other sectors vital to implementing this package include, but are not limited to, education, government (local, state, and federal), social services, health services, business, labor, justice, housing, media, and organizations that comprise the civil society sector such as faith-based organizations, youth-serving organizations, foundations, and other non-governmental organizations. Collectively, these sectors can make a difference in preventing suicide by impacting the various contexts and underlying risks that contribute to suicide.

The strategies and approaches described in this technical package are summarized in Appendix A along with the relevant sectors that are well positioned to lead implementation efforts. For example, business and labor, health care insurers and providers, and government entities are in the best position to implement programs and policies that *Strengthen Economic Supports and Access to Mental Health Care*. These types of supports go beyond individual behavior change and require commitment and support from those sectors that can directly address some of the underlying risks and the environmental contexts that increase the risk for suicide. Public health entities can play an important role by gathering and synthesizing information to inform policy, raise awareness, and evaluate the effectiveness of various policies. Moreover, partnerships with non-governmental and community organizations can be instrumental in increasing awareness of and garnering support for policies affecting individuals and families.

The public health sector has been at the forefront of many community-based prevention efforts, working collaboratively with schools and community-based organizations, to change social norms and positively impact health behavior. Public health is well suited to take on a similar leadership role in *Promoting Connectedness* through peer norm and community engagement activities and supporting the development, evaluation, and adoption of effective programs that *Teach Coping and Problem-Solving Skills* to prevent suicide from happening in the first place. These programs are often delivered in school and community settings, making education and non-governmental organizations vital partners in prevention.

Businesses, workplaces, and local and state government entities, on the other hand, are in the best position to establish policies and support practices that *Create Protective Environments* where people live, work, and play. Public health entities can play an important role by gathering and synthesizing information, working with other agencies within the executive branch of their state or local government in support of policy and other approaches, and evaluating the effectiveness of measures taken. In a similar fashion, public health entities can partner with schools, workplaces, and community organizations to implement and evaluate prevention programs, policies and practices geared toward creating safe, healthy, and supportive environments.

Finally, this technical package includes a number of interventions delivered in hospital, primary care, behavioral health care, and community settings designed to *Identify and Support People At-Risk* and to *Lessen Harms and Prevent Future Risk*. The intensity and activities of these interventions require the expertise of professionals who are licensed and trained to deliver critical intervention support. The health care, social services, and justice sectors can work collaboratively to support individuals at high-risk for suicide and their families. These activities also require coordination of supports across various service providers and community organizations.

Regardless of strategy, action by many sectors will be necessary for the successful implementation of this package. In this regard, all sectors can play an important and influential role in preventing suicide from happening in the first place and lessening the immediate and long-term harms of suicidal behavior by helping those in times of crisis get the services and support they need.

## Monitoring and Evaluation

Monitoring and evaluation are necessary components of the public health approach to prevention. It is important to have timely and reliable data to monitor the extent of the problem and to evaluate the impact of prevention efforts. Data are necessary for program implementation; planning, implementation, and assessment all rely on accurate measurement of the problem.

Surveillance data helps researchers and practitioners track changes in the burden of suicide. Surveillance systems exist at the federal, state, and local levels. It is important to assess the availability of surveillance data and data systems across these levels to identify and address gaps in the systems. CDC's National Vital Statistics System and the National Violent Death Reporting System (NVDRS) are examples of surveillance systems that provide data on deaths from suicide. NVDRS, for example, is a state-based surveillance system that combines data from death certificates, law enforcement reports, and coroner or medical examiner reports to provide detailed information on the circumstances of violent deaths, including suicide, which can assist communities in guiding prevention approaches (Blair, Fowler, Jack, & Crosby, 2016). The National Electronic Injury Surveillance System-All Injury Program (NEISS-AIP) provides nationally representative data about all types and causes of nonfatal injuries treated in U.S. hospital emergency departments, and can be used to assess national rates of, and trends in, self-harm injuries by cause (e.g., falls, poisoning, etc.), age, race/ethnicity, sex, disposition (where the injured person goes when released from the Emergency Department).

In addition to information on deaths and nonfatal injuries, there are also surveillance systems that provide national, state, and some local estimates of suicidal behavior. The Youth Risk Behavior Surveillance System (YRBSS) collects information from a nationally representative sample of 9-12 grade students and is a key resource in monitoring health-risk behaviors among youth, including whether youth have seriously considered attempting suicide, attempted suicide, made a plan, or required treatment by a doctor or nurse for a suicide attempt that resulted in an injury, poisoning, or overdose (Brener et al., 2013). The YRBSS data are obtained from a national school-based survey conducted by CDC as well as school-based state, territorial, tribal, and large urban school district survey conducted by education and health agencies. The National Survey on Drug Use and Health (NSDUH) is an annual nationwide survey of individuals aged 12 years and older that provides national and state-level estimates of drug use and mental health-related issues, including suicide ideation and suicide attempts.

It is also important at all levels (local, state, and federal) to address gaps in responses, track progress of prevention efforts and evaluate the impact of those efforts, including the impact of this technical package. Evaluation data, produced through program implementation and monitoring, is essential to provide information on what does and does not work to reduce rates of suicide and its associated risk and protective factors. Theories of change and logic models that identify short, intermediate, and long-term outcomes are an important part of program evaluation.

The evidence-base for suicide prevention has advanced greatly over the last few decades. However, additional research is needed to understand the impact of prevention programs on preventing suicide, as opposed to merely examining the effectiveness of programs to impact risk factors associated with suicide. More research is also needed to examine the effectiveness of upstream and community-level strategies to prevent suicide at the population level. Lastly, it will be important for researchers to test the effectiveness of combinations of the strategies and approaches included in this package. Most existing evaluations focus on approaches implemented in isolation. However, there is potential to understand the synergistic effects within a comprehensive prevention approach. Additional research is needed to understand the extent to which combinations of strategies and approaches result in greater reductions in suicide than individual programs, practices, or policies.

## Conclusion

Suicide is a serious public health problem whose rates have been on the rise for more than a decade and whose costs stretch well into the billions of dollars each year. And while suicide is a rare outcome statistically, its human impact has a ripple effect that is far-reaching. Each of us likely interacts with suicide survivors, those with lived experience, and those with thoughts of suicide, on a daily basis—at home, at work, and in our communities. Suicide and suicide attempts are therefore public health issues of societal concern. Fortunately, like many public health problems, suicide is preventable, and fortunately more is being done to prevent suicide than ever before, as evidenced by the work of the National Action Alliance for Suicide Prevention, the release of the first world report on suicide, and more timely surveillance data, to name just a few examples. Unfortunately and unlike most other public health problems, suicide still struggles against stigma, shame, and secrecy related to help-seeking, mental illness, being a survivor, or someone with lived experience; misplaced fear of asking someone about their risk of suicide (versus the fear and consequence of not asking), and fear of taking up certain strategies known to be effective but perhaps unpopular; misinformation about suicide preventability, and disproportionate funding given the public health burden. Suicide also struggles against the right degree of awareness where too much information, for example by well-meaning reporters and others, may actually do harm.

In an effort to continue pushing the field and society further towards prevention, this technical package includes strategies and approaches that ideally would be used in a comprehensive fashion, in combination—in a multi-level, multi-sectoral way. This technical package includes strategies and approaches targeting upstream prevention, e.g., social emotional learning for children and youth, as well as strategies focused more downstream, e.g., cognitive behavioral treatment to prevent re-attempts. It includes universal, selective, and indicated strategies, or strategies that focus on the whole population regardless of risk to strategies that focus on those groups at highest risk. Importantly, this technical package extends the bounds of the typical prevention strategies to consider approaches at the outer

levels of the social ecology, e.g., policies to stabilize housing and community engagement initiatives. In short, care and attention has been paid to all aspects of suicide prevention.

While the evidence base continues to be built, the collection of programs, policies, and practices laid out here are available for implementation now. And in keeping with good public health practice, the intent is that monitoring and evaluation will play a key role in that implementation. Moreover, as new evidence becomes available, this technical package can be refined to reflect the current state of the science.

In closing, and in keeping with a message of resilience as spoken by those with lived experience, ‘hope, help, and healing is possible.’

## Appendix A: Summary of Strategies and Approaches to Prevent Suicide

Strategy	Approach/Program, Practice or Policy	Best Available Evidence			Lead Sectors <sup>1</sup>
		Suicide	Suicide Attempts or Ideation	Other Risk/Protective Factors for Suicide	
Strengthen economic supports	<b>Strengthen household financial security</b>				Government (local, state, Federal)
	<i>Unemployment benefit programs</i>	✓			
	<i>Other income supports</i>	✓			Business/labor
	<b>Housing stabilization policies</b>				Government (local, state, Federal)
	<i>The National Neighborhood Stabilization Program</i>			✓	
Strengthen access to mental health care	<b>Coverage of mental health conditions in health insurance policies</b>				Health care
	<i>Mental Health Parity Laws</i>	✓		✓	Government (state, Federal)
Establish protective environments	<b>Reducing access to lethal means among persons at-risk</b>				Government (local, state)
	<i>Intervening at hot spots</i>	✓			
	<i>Safe storage practices</i>		✓	✓	Public Health
	<b>Organizational policies and culture</b>				Business/Labor
	<i>Together for Life</i>	✓			Government (local, state, Federal)
	<i>US Air Force Suicide Prevention Program</i>	✓		✓	

		Best Available Evidence			
	<b>Community-based policies to reduce excessive alcohol use</b>				Government (local, state)
	<i>Alcohol outlet density</i>	✓		✓	Business/labor
<b>Promote connectedness to protect against suicide</b>	<b>Peer norm approaches</b>				Public Health
	<i>Sources of Strength</i>			✓	Education
	<b>Community-engagement activities</b>				Public Health
	<i>Greening vacant urban spaces</i>			✓	Government (local)
<b>Teach coping and problem-solving skills</b>	<b>Social emotional learning</b>				Public Health
	<i>Youth Aware of Mental Health Program</i>		✓		Education
	<i>Signs of Suicide</i>		✓	✓	
	<i>Good Behavior Game</i>		✓	✓	
	<b>Parenting skill and family relationship approaches</b>				Public Health
	<i>The Incredible Years</i>			✓	Education
	<i>Strengthening Families 10-14</i>			✓	
	<b>Gatekeeper training</b>				Public Health
	<i>Mental Health First Aid</i>			✓	Healthcare

		Best Available Evidence			
Identify and support people at-risk	Screening combined with care management				Healthcare
	Henry Ford Perfect Depression Care (Precursor to Zero Suicide)	✓		✓	Social Services
	Crisis Intervention				Public Health
	National Suicide Prevention Lifeline		✓	✓	Social Services
	Applied Suicide Intervention Skills Training		✓	✓	
Intervene to lessen harms and prevent future risk	Treatment for people at risk of suicide				Healthcare
	Improving Mood – Promoting Access to Collaborative Treatment (IMPACT)		✓	✓	Social Services
	Collaborative Assessment and Management of Suicidality (CAMS)		✓	✓	Justice
	Dialectical Behavioral Therapy		✓	✓	
	Attachment-Based Family Therapy		✓		
	Treatment to prevent re-attempts				Healthcare
	ED Brief Intervention with Follow-up Visits	✓			Social Services
	Active follow-up contact approaches	✓	✓		
	CBT for Suicide Prevention				

		Best Available Evidence			
	<b>Postvention</b>				Healthcare
	<i>StandBy Response Service</i>		✓		
	<b>Safe messaging following a suicide</b>				Public Health
	<i>Media Guidelines</i>	✓			Media

<sup>1</sup>This column refers to the lead sectors well positioned to bring leadership and resources to implementation efforts. For each strategy, there are many other sectors such as non-governmental organizations that are instrumental to prevention planning and implementing the specific programmatic activities.

## Overview

This technical package represents a select group of strategies based on the best available evidence to help communities and states sharpen their focus on prevention activities with the greatest potential to prevent suicide. Broadly, the strategies represented include those with a focus on preventing suicide from happening in the first place as well as approaches to lessen the immediate and long-term effects of suicidal behavior for individuals, families, communities, and society. Specifically, the strategies include strengthening economic supports; strengthening access to mental health care; establishing protective environments; promoting connectedness to protect against suicide; teaching coping and problem-solving skills; identifying and supporting people at-risk; and intervening to lessen harms and prevent future risk.

This package supports the National Strategy for Suicide prevention, Goal 1, "Integrate and coordinate suicide prevention activities across multiple sectors and settings." (p.29) It also supports the National Action Alliance for Suicide Prevention's priority "To create and disseminate a framework for comprehensive community-based suicide prevention." (<http://actionallianceforsuicideprevention.org/priorities>)

Commitment, cooperation, and leadership from numerous sectors, including public health, education, justice, health care, social services, business/labor, and government can bring about the successful implementation of this package.

### What is a Technical Package?

A technical package is a compilation of a core set of strategies to achieve and sustain substantial reductions in a specific risk factor or outcome (Frieden, 2014). Technical packages help communities and states prioritize prevention activities based on the best available evidence. This technical package has three components. The first component is the **strategy** or the preventive direction or actions to achieve the goal of preventing suicide. The second component is the **approach**. The approach includes the specific ways to advance the strategy. This can be accomplished through *programs, policies, and practices*. The approaches included come primarily from studies based in the United States. The evidence for each of the approaches in preventing suicide or its associated risk factors is included as the third component. This package is intended as a resource to guide and inform prevention decision-making in communities and states.

### Preventing Suicide is a Priority

Suicide, as defined by the CDC, is part of a broader class of behavior called *self-directed violence*. Self-directed violence refers to behavior directed at oneself that deliberately results in injury or the potential for injury (1). Self-directed violence may be *suicidal* or *non-suicidal* in nature. For the purposes of this document, we refer only to behavior where suicide is intended.

Comment [A]: Changed the word "harms" here to effects since we use harms in the next sentence.

Comment [A]: New sentences

Comment [A]: New sentence

- **Suicide** is a death caused by self-directed injurious behavior with any intent to die as a result of the behavior.
- **Suicide attempt** is defined as a *non-fatal* self-directed and potentially injurious behavior with any intent to die as a result of the behavior. A suicide attempt may or may not result in injury.

### **Suicide is highly prevalent.**

Suicidal behavior presents a major challenge to public health in the United States and worldwide. It contributes to premature death, morbidity, lost productivity, and health care costs (2, 3). In 2014 in the U.S., the most recent death data available, suicide was responsible for 42,773 deaths, which is approximately a suicide every 12 minutes (4). In 2014, suicide ranked as the tenth leading cause of death and has been among the top twelve leading causes of death since 1975 in the U.S. (5) Overall suicide rates have increased from 1999 to 2014 (24% increase) (6). Suicide is a problem throughout the life span; it is the second leading cause of death among those aged 10–19 years, also second among persons in their 20s and 30s; it is the fourth leading cause among persons in their 40s and seventh among persons in their 50s (4).

Suicides reflect only a portion of the number of persons affected by suicidal thoughts and behaviors (7). Substantially more persons are hospitalized as a result of nonfatal suicidal behaviors than are fatally injured, and an even greater number are either treated in ambulatory settings or not treated at all (7). For example, during 2014, among adults aged  $\geq 18$  years, for every one suicide there were 9 adults treated in hospital emergency departments for self-inflicted injuries, 27 who reported making a suicide attempt, and over 227 who reported seriously considering suicide (8). Suicides, attempts, and ideation take an immense emotional, physical, and economic toll on individuals, families and communities. By one estimate, for every death by suicide six people are directly impacted (i.e. survivors). Based on this figure it is estimated that there are over 13 million survivors in the U.S. and unfortunately, survivorship itself is a risk factor for suicide (9).

**Suicide is associated with several risk and protective factors.** Suicide, like other human behaviors, is complex with no single determining cause. It occurs in response to multiple biological, psychological, interpersonal, environmental and societal influences that interact with one another and act cumulatively to increase one's vulnerability to think about or engage in suicidal behaviors. The social-ecological model is a useful framework for viewing and understanding suicidal risk factors that have been identified in the literature<sup>1</sup>:

#### Risk Factors for Suicide<sup>2,3</sup>

- ❑ **Individual:** History of depression and other mental illnesses, alcohol and drug abuse, previous suicide attempt, previous victimization, acute and chronic stressors (e.g. financial problems), genetic and biological determinants, hopelessness
- ❑ **Relationship:** High conflict or violent relationships, sense of isolation and lack of social support, family history of suicide, financial and work stress
- ❑ **Community:** Inadequate community connectedness, barriers to health care-- lack of access to providers or medications
- ❑ **Societal:** Availability of lethal means of suicide, unsafe media portrayals of suicide, stigma associated with help-seeking

An individual having or experiencing one or a number of risk factors does not always lead to suicide; for example, the vast majority of individuals who are depressed do not die by suicide. It is also important to note that these risk factors described above is not an exhaustive list. These and many other risk factors exist and can be arranged differently or contribute to multiple areas within the social-ecological model. Furthermore, the relevance of each risk factor can vary by age, race, gender, sexual orientation, residential geography, and socio-cultural and economic status<sup>2,3</sup>.

Protective factors for suicide: Protective factors, or those influences that guard against the risk for suicide, can also be found across the different levels of the social-ecological model and may vary in significance depending on the context in which the suicide occurs. Protective factors identified in the literature include: effective coping and problem solving skills, moral objections to suicide, strong and supportive relationships with partners, peers, and family, connectedness to school, community and other social institutions and the availability of physical and mental health care<sup>2,3</sup>. These protective factors can either counter a specific risk factor or guard against a number of risks associated with suicide.

### **Suicide is connected to other forms of violence.**

Suicide is connected to other forms of violence in a number of different ways. First, suicide and other forms of violence often share some of the same root causes. They can all take place under one roof, or in a given community or neighborhood and can happen at the same time or at different stages of life.<sup>i,ii</sup> For example, in neighborhoods where there is low cohesion, or where residents don't support and trust each other, people are at higher risk for suicide<sup>iii</sup> as well as perpetration of child maltreatment,<sup>iv,v</sup> teen dating violence,<sup>vi</sup> intimate partner violence,<sup>vii</sup> and youth violence.<sup>viii</sup> Lack of economic opportunities and unemployment are associated with suicide,<sup>ix,x</sup> as well as perpetration of child maltreatment,<sup>xi</sup> intimate partner violence,<sup>xii,xiii</sup> sexual violence<sup>xiv</sup> and youth violence.<sup>xv</sup> Also, while most people who are victims of violence do not act violently or die by suicide, people who experience or are exposed to suicide are at a higher risk for both being a victim of other forms of violence and for inflicting harm on others. For example, children who experience physical abuse or neglect early in their lives are at greater risk for suicide,<sup>xvi</sup> and also at greater risk for committing violence against peers (particularly for boys),<sup>xvii</sup> bullying,<sup>xviii</sup> teen dating violence,<sup>xix</sup> and committing child abuse,<sup>xx</sup> elder abuse,<sup>xxi</sup> intimate partner violence,<sup>xxii</sup> and sexual violence<sup>xxiii</sup> later in life. There are also a number of protective factors that pose an opportunity to protect individuals and communities from suicide and other forms of violence, and buffer the effects of shared risk factors. For example, connectedness increases peoples' and communities' resilience to suicide and other forms of violence, including connectedness to one's community,<sup>xxiv,xxv,xxvi,xxvii,xxviii,xxix,xxx</sup> school,<sup>xxxi,xxxii,xxxiii,xxxiv,xxxv,xxxvi</sup> family,<sup>xxxvii,xxxviii,xxxix, xl,xli</sup> caring adults,<sup>xlii,xliii,xliv</sup> and pro-social peers.<sup>xlvi,xlv</sup>

### **The health and economic consequences of suicide are substantial.**

Total lifetime costs associated with nonfatal injuries and deaths caused by self-directed violence in 2013 were approximately \$93.5 billion after adjusting for under-reporting of suicide (10).

### **Suicide can be prevented.**

Despite the myths surrounding suicide, like most public health problems, suicide is preventable. And while progress will continue to be made into the future, evidence for numerous programs, practices, and policies currently exist and are ready to be implemented now. Just as suicide is not caused by a single factor, research suggests that suicide will not be prevented by any single intervention taking place in any single setting. Rather, suicide prevention is best achieved by a focus across the individual-, relationship-, family-, community, and societal-levels and across all sectors, private and public (e.g., business, public health, physical and behavioral healthcare, justice, education, labor). According to CDC Director, Tom Frieden, successful public health programs also require political commitment, funding, communication, and performance monitoring.

## **Assessing the Evidence**

This technical package includes programs, practices, and policies with evidence of impact on suicide or risk or protective factors for suicide. To be considered for inclusion in the technical package, the program, practice, or policy selected had to meet at least one of these criteria: a) meta-analyses or systematic reviews showing impact on suicide; b) evidence from at least one rigorous (e.g., randomized controlled trial [RCT] or quasi-experimental design) evaluation study that found significant preventive effects on suicide; c) meta-analyses or systematic reviews showing impact on risk or protective factors for suicide, or d) evidence from at least one rigorous (e.g., RCT or quasi-experimental design) evaluation study that found significant impacts on risk or protective factors for suicide. Finally, consideration was also given to the likelihood of achieving beneficial effects on multiple forms of violence; no evidence of harmful effects on specific outcomes or with particular subgroups; and feasibility of implementation in a U.S. context if the program, policy, or practice has been evaluated in another country.

Within this technical package, some approaches do not yet have research evidence demonstrating impact on rates of suicide but instead are supported by evidence indicating impacts on risk or protective factors for suicide (e.g., help-seeking, stigma reduction, depression, connectedness). In terms of the strength of the evidence, programs that have demonstrated effects on suicidal behavior (e.g., reductions in deaths, attempts) provide a higher-level of evidence, but the evidence base is not that strong in all areas. For instance, there has been less evaluation of community engagement and family programs on suicidal behavior. Thus, approaches in this package that have effects on risk or protective factors reflect the developmental nature of the evidence base and the use of the best available evidence at a given time.

It is also important to note that there is often significant heterogeneity among the programs, policies, or practices that fall within one approach or strategy area in terms of the nature and quality of the available evidence. Not all programs, policies, or practices that utilize the same approach (e.g., gatekeeper training) are equally effective, and even those that are effective may not work across all populations. Tailoring programs and more evaluation may be necessary to address different population groups. The examples provided are not intended to be a comprehensive list of evidence-based programs, policies, or practices for each approach, but rather illustrate models that have been shown to impact suicide or have beneficial effects on risk or protective factors for suicide. In practice, the effectiveness of the programs, policies and practices identified in this package will be strongly dependent on the quality of their implementation and the communities in which they are implemented. Implementation guidance to assist practitioners, organizations and communities will be developed separately.

### Context and Cross-Cutting Themes

The strategies and approaches that have been included in this technical package represent different levels of the social ecology, with efforts intended to impact the community and societal levels, as well individual and relationship levels. The strategies and approaches are intended to work in combination and reinforce each other to prevent suicide (see box below). The strategies are arranged in order such

that those strategies hypothesized to have the greatest potential for broad public health impact on suicide are included first, followed by those that might impact more select populations (e.g., persons who have already made a suicide attempt).

Preventing Suicide	
Strategy	Approach
Strengthen economic supports	<ul style="list-style-type: none"> <li>Strengthen financial security</li> <li>Housing stabilization policies</li> </ul>
Strengthen access to mental health care	<ul style="list-style-type: none"> <li>Coverage of mental health conditions in health insurance policies</li> </ul>
Establish protective environments	<ul style="list-style-type: none"> <li>Means restriction</li> <li>Organizational policies and culture</li> <li>Community-based policies to reduce excessive alcohol use</li> </ul>
Promote connectedness to protect against suicide	<ul style="list-style-type: none"> <li>Peer norm approaches</li> <li>Community engagement activities</li> </ul>
Teach coping and problem-solving skills	<ul style="list-style-type: none"> <li>Social-emotional learning</li> <li>Parenting skill and family relationship approaches</li> </ul>
Identify and support people at risk	<ul style="list-style-type: none"> <li>Gatekeeper training</li> <li>Screening combined with care management</li> <li>Crisis intervention</li> </ul>
Intervene to lessen harms and prevent future risk	<ul style="list-style-type: none"> <li>Treatment for people at-risk of suicide</li> <li>Treatment to prevent re-attempts</li> <li>Postvention</li> <li>Safe messaging following a suicide</li> </ul>

The example programs, policies, and practices have been implemented within particular contexts. The social and cultural context of communities is critically important to take into account when selecting strategies and approaches. Practitioners in the field may be in the best position to assess the needs and strengths of their communities and work with community members to make decisions about the combination of approaches included here that are best suited to their context.

[Add text for other issues to potentially cover in this section. You may want to take a look at the other packages in this regard]

This package includes strategies where public health agencies are well positioned to bring leadership and resources to implementation efforts. It also includes strategies where public health can serve as an important collaborator (e.g., strategies addressing community and societal level risks), but where leadership and commitment from other sectors such as business/labor or health care is critical to implement a particular policy or program (e.g., workplace policies; screening combined with care management). The role of various sectors in the implementation of a strategy or approach in preventing suicide is described further in the section on *Sector Involvement*.

In the sections that follow, the strategies and approaches with the best available evidence for preventing suicide are described.

## Strengthen Economic Supports

### Rationale

### Approaches

Brief statement introducing the approaches (see example statements in the other technical packages).

- **Strengthen household financial security.** Research indicates that economic crises are related to suicide rates. Findings from the U.S. show that suicide rates increase during economic recessions marked by high unemployment rates, job losses, and economic instability and decrease during economic expansions and periods marked by low unemployment rates, particularly for working-age individuals 25 to 64 years old (Luo et al., 2011; Fowler et al., 2015). Policies that support financial security during difficult economic times have been shown to mitigate the risk of economic crises on suicide rates.
- **Housing stabilization policies** that aim to strengthen housing stability and security may help to buffer the impact of foreclosures and evictions on suicide, as recent research has drawn an association between housing instability and suicidal behavior. Programs that provide affordable housing and other options for homebuyers such as loan modification programs may be used in conjunction with move-out planning and financial counseling services to minimize the impact of foreclosures and evictions on suicide.

### Potential Outcomes

- 
- 
- 

### Evidence

Brief statement introducing the evidence [see example statements in the other technical packages].

- **Strengthen household financial security.**

- **Housing stabilization policies.**

## Strengthen Access to Mental Health Care

### Rationale

Mental illness is a risk factor for suicide. Studies suggest that up to 90% of people who die by suicide may have had a mental illness (Cavanaugh et al., 2003). Research on state-level suicide rates have been found to be correlated with general mental health measures such as depression (Arsenault-Lapierre, et al., 2004). While most people with mental health problems do not attempt or die by suicide, assuring access to quality mental health care is critical to suicide prevention.

### Approaches

A major approach to strengthening access to mental health care is to have health insurance policies that include coverage for such services.

- **Coverage of mental health conditions in health insurance policies.** Health insurance policies that allow people with mental health problems to access mental health treatment in the same way that they access health care for physical health concerns can increase use of mental health services, help normalize treatment seeking in the population, reduce symptoms of mental illnesses like depression and bipolar disorder, and in turn, reduce rates of suicide and suicide attempts.

### Potential Outcomes

- Increased access to mental health services
- Decreased symptoms of mental illnesses
- Decreased rates of suicide attempts
- Decreased rates of suicide

### Evidence

Brief statement introducing the evidence.

- **Coverage of mental health conditions in health insurance policies.**  
Using data from the National Survey of Drug Use and Health, Harris et al. (2006) found that 12 months after states enacted parity laws, self-reported use of mental healthcare services significantly increased. Subsequent research by Lang et al. (2011), suggests that mental health parity laws are associated with an approximate 5% reduction in suicide rates. This reduction (in 29 states) equated to the prevention of 592 suicides per year and a cost savings of \$1.3-3.1 million per suicide prevented (Lang, 2013).

## Establish Protective Environments

### Rationale

Suicide prevention efforts that focus on *both* the individual *and* his/her environment increase the likelihood of lives saved. Establishing protective environments helps ensure that all of the places where an individual lives, works, and plays are supportive. Limiting access to lethal means, be it at home or in nature, and particularly when an individual may be most vulnerable, can literally make the difference between life and death. Likewise, creating a work environment conducive to prevention and focused on employee well-being supports the large majority of the population where they spend much of their day. Finally, policies that reduce the availability of alcohol, a potent suicide risk factor, serve to support individuals and protect the environment further.

### Approaches

The current evidence suggests three approaches with promise for creating environments that protect against suicide. These include:

- **Means Restriction.** Modifying the environment to decrease access to lethal means is an important public health strategy for preventing suicide. Acute suicidal crises are often brief and impulsive. Previous research indicates that the interval between thinking about suicide and attempting can be as short as 5-10 minutes (Simon et al., 2001; Deisenhammer et al., 2009). Getting past the impulse by making it more difficult to access lethal means can be lifesaving. Highly lethal means such as firearms, hanging/suffocation, or jumping from heights provide little opportunity for rescue and have high fatality rates (e.g., about 85% of people who use a firearm in an attempt die from their injury). Research also indicates that most people tend not to substitute a different method when a highly lethal method is unavailable or difficult to access (Hawton, 2007; Yip et al., 2012). Removing or restricting access to lethal means changes the context of the potential suicide and whether the outcome will be fatal or non-fatal (Yip et al., 2012).
  - *Intervening at Suicide Hotspots.* These interventions are focused on preventing suicides at locations which offer direct means for suicide or a secluded place that prevents intervention. Suicide hotspots include tall structures (for example, bridges and cliffs), railway tracks, and isolated locations that are popular destinations for suicide (for example, parks). Interventions include barriers to prevent jumping and signs and telephones to encourage suicidal individuals to seek help.
  - *Safe Storage Practices* for medications, firearms, and other household products can reduce the risk for suicide by preventing impulsive action and separating individuals from easy access to lethal means. Safe storage practices include education and counseling around storing firearms locked in a secure place (e.g., in a gun safe or lock box), preferably unloaded and separate from the ammunition. Keeping medicines in a

locked cabinet or secure location can also prevent their misuse by children and adolescents.

- **Organizational policies and culture** that focus on prosocial behavior, skill building, changing social norms, referral and access to helping services (e.g. mental health, substance abuse treatment, financial counseling), and that have leadership support from the top down can positively impact organizational climate and morale and help prevent suicide and its related risk factors (e.g. depression, social isolation).
- **Community-based policies to reduce excessive alcohol use.** Acute alcohol use has been found to be associated with more than one-third of suicides and approximately 40% of suicide attempts (Cherpitel, Borges & Wilcox, 2004). While various community policies exist to reduce excessive alcohol use (e.g., zoning limits related to alcohol outlet locations and density, taxes on alcohol, and bans on the sale of alcohol for individuals under the legal drinking age), previous research indicates that policies related to outlet locations and density are more strongly associated with suicide, making these particular policies an important approach to preventing suicide.

### Potential Outcomes

- Increase in safe storage of lethal means
- Reduction in suicide attempts
- Reduction in suicide deaths
- Reduction in alcohol-related suicide deaths

### Evidence

The evidence for the effectiveness of means restriction and other ways to establish protective environments is some of the strongest in the field (Zalsman et al., 2016).

- **Means restriction**
  - *Intervening at suicide hotspots* A meta-analysis of suicide hotspot interventions implemented in combination or in isolation in the U.S. and abroad found they reduced suicide (Pirkis et al., 2015; Cox, 2013). For example, suicide deaths from jumping from the Jacques-Cartier bridge in Canada decreased after the installation of a bridge barrier (incidence rate ratio [IRR] = 0.24; 95% confidence interval [CI] = 0.13, 0.43), which persisted when all bridges (IRR = 0.39; 95% CI = 0.27, 0.55) and all jumping sites (IRR = 0.66; 95% CI = 0.54, 0.80) in the regions were considered, suggesting little or no displacement to other jumping sites (Perron, et. al., 2013). In contrast, the

removal of safety barriers on the Grafton Bridge in Auckland, New Zealand led to an immediate and substantial increase in both the numbers and rate of suicide by jumping from the bridge from 3 to 15 ( $p < 0.01$ ); the rate of such deaths also increased ( $p < 0.01$ ; Beautrais, 2001; Beautrais, et. al., 2009).

- *Safe storage practices* In a case-control study of firearm-related events identified by medical examiner and coroner offices from 37 counties in Washington, Oregon, and Missouri, and 5 trauma centers, Grossman et al., (2005) found that safe storage practices (i.e., storing firearms unloaded, separate from ammunition, in a locked place and/or secured with a safety device) were protective for suicide attempts among adolescents (Grossman et al., 2005). A recent systematic review of clinic and community-based education and counseling around safe storage of firearms found that the provision of safety devices significantly increases safe firearm storage practices compared to counseling alone or providing economic incentives to acquire safety devices (Rowhani-Rahbar, Simonetti, & Rivara, 2016). The *Emergency Department Counseling on Access to Lethal Means (ED CALM)* program trained psychiatric emergency clinicians in a large children's hospital to provide lethal means counseling and safe storage boxes to parents of patients under age 18 receiving care for suicidal behavior. In a pre-post study, Runyan et al (2015) found that among the parents contacted at follow-up, 76% reported all medications in the home were locked up as compared to fewer than 10% at the time of the initial emergency department visit. Among parents who indicated the presence of guns in the home at the time of the child's initial emergency department visit, all reported guns were currently locked, compared to 67% reporting this at the time of the initial visit.
- **Organizational policies and culture** *Together for Life* is a workplace program of the Montreal Police Force implemented to address suicide among officers. Policy and program components of *Together for Life* were designed to foster an organizational culture that promoted mutual support and solidarity among members of the Force, help for problems related to suicide, training of supervisors, managers and all units to improve competencies in identifying suicidal risk and in using existing resources, and an education campaign to improve awareness and help-seeking. After implementation of the program, police suicides were tracked over 12 years and compared to rates in the control city of Quebec. Pre-post assessments of learning, interviews, and focus groups were also included. The suicide rate in the intervention group decreased significantly by 78.9% ( $p < .008$ ) to 6.42 per 100,000 per year compared to 29.0 per 100,000 in the control city--a significant difference in rates ( $p < .007$ ) (Mishara & Martin, 2012).

*The United States Air Force Suicide Prevention Program (AFSPP)*, inclusive of 11 policy and education initiatives, was designed to change the culture of the Air Force surrounding suicide. The program uses leaders as role models and agents of change, establishes expectations for behavior related to awareness of suicide risk, develops population skills and knowledge (i.e., education and training), and investigates every suicide (i.e., outcomes measurement). The program represents a fundamental shift from viewing suicide and mental illness solely as medical problem and instead sees them as larger service-wide problems impacting the whole community. Using a time-series design, the *AFSPP* program

was associated with a 33% relative risk reduction in suicide (Knox et al., 2003). The program was also associated with relative risk reductions in related outcomes including moderate and severe family violence (30% and 54%, respectively), homicide (51%), and accidental death (18%); Knox et al., 2003). A longitudinal assessment of the program over the period 1981 to 2008 (16 years before the 1997 launch of the program and 11 years post-launch) found significantly lower rates of suicide after the program was launched than before (Knox et al., 2010). These effects were sustained over time, except in 2004, which the authors found was associated with less rigorous implementation in that year than in the other years (Knox et al., 2010).

- **Community-based policies to reduce excessive alcohol use** Several studies on alcohol outlet density in the United States have found that greater alcohol availability is positively associated with alcohol-involved suicides (Giesbrecht et al., 2014; Escobedo & Ortiz, 2002). For example, Giesbrecht et al. (2014) found that both on and off-premises alcohol outlets (i.e., restaurants where alcohol is served and stores where alcohol is available for purchase to go) were positively associated with alcohol-related suicides in 14 U.S. states, particularly among men (AOR 1.08, CI=1.03-1.13) and American Indian/Alaska Natives (AOR= 1.36; CI= 1/10-1.69). Additionally, a longitudinal analysis of alcohol outlet density, suicide mortality, and hospitalizations for suicide attempts over 6 years in 581 California zip codes indicated that the density of bars, specifically, is related to suicide and suicide attempts, particularly in rural areas (Johnson, Gruenewald & Remer, 2009). These findings suggest that measures to reduce alcohol outlet density can potentially reduce alcohol-involved suicides.

## Promote Connectedness to Protect Against Suicide

### Rationale

The quantity and quality of our social connection with others has been linked with suicide dating as far back to Durkheim, who first posited that the weakening social bonds is among the chief causes for suicidality<sup>1</sup>. Connectedness is the degree to which an individual or group of individuals are socially close, interrelated, or share resources with others<sup>2</sup>. Connectedness can be formed within and between multiple levels of the social ecology<sup>3</sup>; for instance between individuals (e.g. peers, neighbors, co-workers), families, schools, neighborhoods, workplace, faith communities, cultural groups, and society as a whole. Connectedness is also viewed as a broad term that encompasses several other concepts including social support, social participation, social isolation, social cohesion, social capital, social integration, all of which have been linked to suicidal behaviors either conceptually or scientifically within the literature. Connectedness can serve either to protect or mitigate suicidal behaviors by decreasing isolation, encouraging adaptive coping behaviors, increasing belongingness, personal value and worth all of which helps individuals to build resilience in the face of adversity. Connectedness can also provide individuals with better access to formal supports and resources, mobilize communities to meet the needs of its members and provide collective primary prevention activities to the community as a whole<sup>2</sup>.

[insert info on connectedness and include some or all of the following re social capital here]. Social capital refers to a sense of trust in one's community and neighborhood, social integration, and also the availability and participation in social organizations (Muenning et al., 2013; Beyer et al., 2014). Many ecological cross-sectional and longitudinal studies have examined the impact of aspects of social capital on depression symptoms, depressive disorder, mental health more generally, and suicide. While the evidence is still being built the pattern is towards an inverse association between social capital measured by social trust, community/neighborhood engagement, and improved mental health

### Approaches

The following two approaches are designed to promote connectedness among individuals and within communities to protect against suicide.

- **Peer norm approaches** seek to normalize help-seeking, encourage reaching out and talking to trusted adults, and promote supporting peers through building connectedness. These approaches are typically delivered in school settings but can also be implemented in community settings.

**Comment [A]:** This is what was in the table that Linda said could be added to the rationale.

- **Community engagement activities.** Community engagement is an aspect of social capital and involves residents participating in a range of activities, including religious activities, community clean-up and greening activities, and physical exercise. These activities provide opportunities for residents to become more involved in the community and to connect with other community members, organizations, and resources, resulting in enhanced overall physical health, reduced stress, and decreased depressive symptoms, thereby reducing risk of suicide.

### Potential Outcomes

- Reduction in maladaptive coping attitudes and behaviors
- Increase in healthy coping attitudes and behaviors
- Increase in referrals for youth in distressed
- Increase help-seeking behaviors
- Positive perception of adult support

### Evidence

Brief statement to introduce the evidence.

Current evidence provide some support for these types of approaches for reducing risk factors associated with suicidal behaviors.

- **Peer norm approaches.** Evaluations show that programs such as *Sources of Strength (SOS)* can improve school norms and beliefs about suicide that are created and disseminated by student peers. In a randomized controlled trial of the program conducted with 18 urban and rural high-schools Wyman et al., (2010)<sup>4</sup> found that *SOS* improved peer leaders' knowledge of adult supports for suicidal peers ( $p<.01$ ) and were more likely than untrained leaders to refer distressed peers to adult supports ( $p<.03$ ). Trained peer leaders also reported a greater decrease in maladaptive coping attitudes compared with untrained leaders ( $p<.01$ ).
- **Community-engagement activities.** *Greening vacant urban spaces* is an initiative that communities have adopted, particularly after the Great Recession (2007-2009) when many cities across the U.S. experienced urban abandonment. These initiatives engaged community members in the cleaning, greening, or beautifying vacant areas. One vacant lot greening initiative, which greened 4,436 lots in 4 areas of Philadelphia, PA, greening significantly reduced community residents' self-reported stress levels ( $p<.001$ ) and engaged in more physical exercise ( $p<.001$ ) than residents in control vacant lot areas. Other benefits included reductions in firearm assaults and vandalism<sup>5</sup>.

## Teach Coping and Problem-Solving Skills

### Rationale

Building life skills prepare individuals to successfully tackle every day challenges and adapt to stress and adversity. Life skills encompasses many concepts, but most often include coping and problem-solving skills, conflict resolution, and critical thinking. Life skills are important in shielding individuals from suicidal behaviors<sup>6</sup>. Suicide prevention programs that focus on life and social skills training are drawn from social cognitive theories<sup>7</sup>, surmising that individuals who engage in suicidal behavior is attributed to either direct learning, modeling, and environmental and individual (e.g. hopelessness) characteristics. The literature linking life skills and suicide is robust--- The inability to employ adequate coping strategies to cope with immediate stressors or identify and find solutions for problems have been characterized among suicide attempters<sup>8</sup>. Treatments that include bolstering problem skills<sup>9</sup> and include problem-solving techniques<sup>10,11</sup> appear to reduce suicidal ideation and attempts more effectively. Prevention programs focused on teaching these skills target youth, parents and families and have been used with both universal and at-risk populations. While many do not target suicidal behaviors directly, these programs strive to train youth and parents important life skills to offset the underlying vulnerabilities that contribute to engaging in high risk behaviors early in life.

### Approaches

Current evidence provides support for the following two approaches:

- **Social emotional learning programs** focus on developing and strengthening communication and problem-solving skills, emotion regulation, conflict resolution, help seeking and coping skills. These approaches address a range of risk and protective factors for suicidal behavior. They provide children and youth with skills to resolve problems in relationships, school, and with peers, and help youth to address other negative influences (e.g., substance use) associated with suicide. These approaches are typically delivered to all students in a particular grade or school, although some programs also focus on groups of students considered to be at high-risk for suicide. Opportunities to practice and reinforce skills are an important part of programs that work.
- **Parenting skill and family relationship programs** are designed to strengthen parenting skills, enhance positive parent-child interactions, and improve children's behavioral and emotional skills and abilities. Several parenting and family relationship programs have been shown in rigorous evaluations to improve resilience and reduce risk factors for various behaviors, including ones closely related to suicide, such as depression, internalizing behaviors, and substance abuse.

## Potential Outcomes

- Reduction in suicide attempts and suicide ideation
- Enhanced knowledge of risk and protective factors associated with suicide
- Reduction in suicide risk behaviors (i.e., depression, anxiety, conduct problems, substance abuse)
- Improve and normalize help-seeking behavior
- Enhance social competence and emotional regulation skills
- Enhance problem-solving and conflict management skills

## Evidence

There are several programs with evidence that supports teaching social, emotional and parenting skills to reduce suicidal behaviors and associated risk factors.

- **Social emotional learning programs.** These programs, commonly delivered in schools, overall have demonstrated success in preventing suicide risk. However, the evidence is mixed; while most models demonstrated strong effects, others were mixed. For example, *Signs of Suicide (SOS)* is a high school-based prevention program for students designed to increase knowledge about suicide improve and normalize help-seeking behaviors. After 3 months of participation, *SOS* has documented a 64% reduction in suicide attempts among its participants compared to controls. *SOS* participants with a lifetime history of suicide attempt were also significantly less likely to report planning a suicide in the 3 months following the program compared to lower-risk participants. Moreover, increased knowledge of how access help for themselves or friends for depression and/or suicidal thoughts, and favorable attitudes toward help-seeking were noted among students who participated in *SOS*<sup>12</sup>.

Another example is *The Good Behavior Game (GBG)*, which is a classroom-based program for elementary school children uses a behavior management strategy that promotes good behavior by setting clear expectations for good behavior and consequences for maladaptive behavior. In the evaluation of this program, several outcome behaviors were measured including suicide, given its association with externalizing behavior problems. Results from the first cohort evaluation found that first graders assigned to *GBG* reported half the adjusted odds of suicide ideation and suicide attempts than controls. After 14 years postvention, *GBG* was also found to significantly reduce risk of substance abuse<sup>13</sup>. However, in a replication trial, *GBG* did not produce the same reductions on suicide ideation or attempts as it did in the first cohort<sup>14</sup>. This finding likely arose due to the lack of implementation fidelity and pointed to the need for *GBG* to be delivered with precision, consistency, and teacher support (ref??).

Finally, the *Youth Aware of Mental Health Program (YAM)*, a school-based program rigorously evaluated in 10 European countries, teaches youth about suicide risk and protective factors and problem-solving skills. At 12 months, students participating in *YAM* were significantly less likely to have a suicide attempt and severe suicidal ideation compared to controls; Risk of suicide ideation and attempts fell by 49 to 54% among *YAM* participants<sup>15</sup>.

- **Parenting skill and family relationship programs**

Parenting and family skills training approaches have shown promising impacts in preventing key risk factors associated with suicide. One program, *The Incredible Years* is a universally delivered program for parents of children up to 12 years of age designed to improve responsive and positive parent-teacher-child interactions and relationships, emotion self-regulation and social competence and reduce problem behaviors in children. Several studies have demonstrated the effect of *The Incredible Years* program on reducing internalizing symptoms, such as anxiety and depression, and child conduct problems<sup>16,17,18,19</sup>. The program is also associated with improved problem-solving and conflict management, skills that were maintained at 1-year follow-up<sup>17,18,19</sup>. The program also demonstrated greater benefits as the dosage of the intervention increased<sup>20</sup>. *Strengthening Families 10-14 years* is a program that involves sessions between parents, youth, and family with the goals of: 1) improving parents' skills for disciplining, managing emotions and conflict, and communicating with their children; 2) promoting youths' interpersonal and problem-solving skills; and 3) creating family activities to build cohesion and positive parent-child interactions. The program has successfully shown to decrease externalizing behaviors, alcohol use, and drug use among youth participants and reductions in depression, alcohol use, and drug use among participating families<sup>21</sup>.

## Identify and Support People At-Risk

### Rationale

In order to be successful in decreasing suicidal behavior, attention must be paid to those who are at-risk or vulnerable. These persons experience risk and occurrence of suicidal behavior that is higher than average. This group requires particular focus on proactive case finding and retention and access to services. These vulnerable or disadvantaged populations include (but are not limited to): those living in lower socio-economic status; members of certain ethnic minority groups; those with a mental health problem; those who are institutionalized; those who have been victims of violence; and those who are homeless. Finding effective ways of identifying at-risk or vulnerable groups, customizing services to make them accessible and maintaining care are still key challenges. For example, simply improving services does not guarantee that those services will be used by those most in need of them. Nor will it necessarily increase the number of people who follow treatments that are recommended. People who are disadvantaged face social and economic issues that may adversely affect their ability to respond to the treatments or advice that are offered.

### Approaches

This document outlines three approaches that focus on identifying and supporting those who are at-risk.

- **Gatekeeper training** is typically implemented in schools and within health care settings and is designed to train teachers, coaches, providers and others in the community to identify people who may be at risk of suicide and to respond effectively, including facilitating treatment seeking and support services.
- **Screening combined with care management and overall continuity of care** has been used in primary care and behavioral health care to assure that people who may be at high-risk of suicide don't 'slip through the cracks'. These approaches typically employ screening for depression and/or suicide combined with collaborative treatment planning between patients and their providers and patient follow-up. Programs such as these have demonstrated beneficial effects on depression, suicide ideation, and suicide mortality.
- **Crisis intervention.** These approaches provide support and referral services, typically by connecting a person in crisis (or a friend or family member of someone at-risk) to trained volunteers and/or professional staff via telephone hotline, online chat, or text messaging. Crisis intervention approaches are intended to impact key risk factors for suicide, including feelings of depression, hopelessness, and subsequent mental health care utilization. Like means restriction,

crisis interventions can put space or time between an individual who may be considering suicide and harmful behavior.

### Potential Outcomes

- Reduction in suicide attempts
- Reduction in suicide deaths
- Increased identification of individuals at-risk for suicidal behavior
- Increased at-risk individuals in treatment
- Increased community members trained to identify at-risk individuals
- Increased referrals for health care

### Evidence

- There is evidence that community gatekeeper programs are successful in reducing suicides and suicide attempts but the efforts must be maintained. (Substance Abuse and Mental Health Services Administration, Center for Mental Health Services. Report to Congress: Garret Lee Smith Suicide Prevention Program. US Department of Health and Human Services: Rockville, MD, 2014). There is limited evidence for effectiveness screening programs but standard principles for public health screening make them promising. (Pena JB, Caine ED. Screening as an Approach for Adolescent Suicide Prevention. *Suicide and Life-Threatening Behavior*. 2006; 36(6):614-637. The number of studies evaluating crisis intervention services is limited but a few studies do indicate that those who use the hotline services have decreased suicidal thoughts and behavior.
- **Gatekeeper training.**  
*Mental Health First Aid (MHFA)*, designed for the lay public, consists of three weekly sessions of three hours each. The content covers helping people in mental health crises and/or in the early stages of mental health problems. The crisis situations covered included suicidal thoughts and behavior, acute stress reaction, panic attacks and acute psychotic behavior. The mental health problems discussed included depressive, anxiety and psychotic disorders. The co-morbidity with substance use disorders is also covered. Participants learn the symptoms of these disorders, possible risk factors, where and how to get help and evidence-based effective help. In a randomized controlled trial of 300 participants, the intervention group reported greater confidence in providing help to others, greater likelihood of advising people to seek professional help, improved concordance with health professionals about treatments, and decreased stigmatizing attitudes. An additional finding was an improvement in the mental health of the participants themselves. All results were statistically significant at  $p < .05$ . (Kitchener & Jorm,

2004). Additional research rigorously evaluating MHFA for its impact on the first aid recipients themselves and suicidal behavior is needed (Kitchener & Jorm, 2006).

*Garret Lee Smith (GLS) Suicide Prevention Program*, as of June 2014, 154 GLS grants had been awarded to 49 states and 48 tribes. Gatekeeper training has been a core part of all GLS programs, and grantees have consistently reported spending the largest proportion of their budget on this strategy. A multi-site evaluation assessed the connection between community gatekeeper training (activities such as the number of people trained and the intended mid- and long-term outcomes) and a reduction of suicide attempts and deaths. To address this question, the analysis compared the change in the suicide mortality rates and nonfatal suicidal behavior among the population aged youth and young adults in counties implementing GLS trainings, with the trajectory observed in similar counties that did not implement these trainings. Effect on fatal behavior - When compared with similar counties that did not implement GLS training, counties implementing GLS trainings presented significantly lower youth suicide rates the year following the training implementation (-1.07,  $p=.03$ ). This finding represents a decrease of 1 suicide death per 100,000 10 to 24 year olds or the avoidance of approximately 237 deaths in this age group between 2007 and 2010. Effect on nonfatal behavior - Counties implementing GLS program activities had significantly lower suicide attempt rates among youths 16 to 23 years of age in the year following implementation of the GLS program than did similar counties that did not implement GLS program activities (4.9 fewer attempts per 1000 youths [95% CI, 1.8-8.0 fewer attempts per 1000 youths];  $P = .003$ ). More than 79 000 suicide attempts may have been averted during the period studied following implementation of the GLS program.

Walrath C, Godoy-Garraza L, Reid H, Goldston DB, McKeon R. Impact of the Garrett Lee Smith Youth Suicide Prevention Program on Suicide Mortality. *American Journal of Public Health*: May 2015, Vol. 105, No. 5, pp. 986-993. doi: 10.2105/AJPH.2014.302496.

- **Screening combined with care management and overall continuity of care.**

*Henry Ford Perfect Depression Care (Pre-cursor to Zero Suicide)* The overall goal of the program was to eliminate suicide. More broadly, the aim of the program was to completely redesign depression care delivery to achieve breakthrough improvement in quality and safety. The redesign focused on six aims: effectiveness, safety, patient centeredness, timeliness, efficiency, and equity among patients. The program developed concrete measures to assess progress on each of these aims. The program began with screening and assessment of each patient for suicide

risk with coordinated continuous follow-up care system wide. On the basis of the combined total of 31 suicides for the 11-year observation period, the rate of suicide among patients was 97 per 100,000 (N=13) for the two baseline years (the average rate for 1999 and 2000). This rate is similar to that reported for a clinical population. For the start-up year (2001), the rate of suicide was 41 per 100,000 (N=3). For the follow-up interval (the average for 2002–2009), the rate was 19 per 100,000 (N=15). Poisson regression analysis showed a statistically significant decrease of 82% in the suicide death rate between the baseline (1999–2000) and intervention (2002–2009) years (rate ratio=.20; 95% confidence interval=.16–.24,  $p \leq .001$ ). Coffey et al., 2013; Coffey, 2006. Additionally, between 1999 and 2010, researchers found that suicide rates declined among HMO members who received mental health specialty services, in association with a target prevention effort, and increased among HMO members who accessed general medical services but not specialty MH services (Coffey et. al., 2015).

- **Crisis intervention.**

*National Suicide Prevention Lifeline (NSPL).* This is a nationwide hotline that operates 24/7 and is accessible by phone or a web-based chat function. Trained counselors are on-hand to listen, offer free and confidential emotional support, and provide referrals for mental health services in the local area. Suicide callers (N=1,085) were assessed during their calls to the hotline and 380 (35.0%) participated in the follow-up assessment. Results indicated that seriously suicidal individuals called the hotline. Significant decreases in suicidality were found during the course of the telephone session, with continuing decreases in hopelessness and psychological pain in the following weeks (Gould et al., 2007).

- *Applied Suicide Intervention Skills Training (ASIST).* This a training program for hotline counselors, emergency workers, clergy, caregivers and others in the community. The ASIST model has three phases of caregiving: connecting, understanding and assisting. The training helps participants identify people who are having thoughts of suicide and to recognize their invitation for help (connecting); to listen to the caller's reasons for dying and living (understanding); and how to conduct a safety assessment, develop a safety plan for the person at risk, and connect the person at risk to community resources (assisting). The ASIST training program has been field tested in a variety of settings. In a national randomized controlled trial, Gould et al (2013) assessed the impact of the ASIST training across the NSPL network of hotlines over the period 2008-2009. Data were derived from 1,507 monitored calls from 1,410 suicidal individuals to 17 Lifeline centers. Callers who spoke with ASIST-trained counselors were significantly more likely to feel less depressed, less suicidal, less overwhelmed, and more hopeful by the end of calls compared to those who spoke to counselors receiving usual care training. ASIST-trained counselors were also better able to keep callers on the phone longer and

establish a connection. ASIST training, however, did not yield more comprehensive suicide risk assessments than usual care training (Gould et al., 2013).

## Intervene to Lessen Harms and Prevent Future Risk

### Rationale

Individuals who have experienced mental health challenges, suicidal ideation, and have had non-fatal suicide attempts or have engaged in non-suicidal self-injury are at increased risk of subsequent suicide-related morbidity and mortality. Risk of suicidality can also increase among those who have lost a friend, family member, co-worker, or other acquaintance to suicide. Exposure to sensationalized or uninformed reporting regarding suicide-related deaths may heighten the risk of suicide among vulnerable individuals and can inadvertently contribute to suicide contagion.

### Approaches

A broad array of approaches to lessen harms and reduce future risk of suicidality among those at increased risk include the provision of mental health care and improved continuity of care, improving linkage to care through active post-discharge planning and follow-up that decreases barriers to ongoing therapeutic support, increasing connectedness to supportive others, addressing bereavement, and framing communications to emphasize resilience, decrease negative affect, and to prevent contagion.

- **Treatment for people at-risk of suicide** typically includes various forms of psychotherapy delivered by licensed providers to help individuals with mental health problems and other risk factors for suicide with problem-solving, impulsivity and emotion regulation.
- **Treatment to prevent re-attempts.** These follow-up contact approaches use diverse modalities (e.g., home visits, mail, telephone, e-mail) to engage recent suicide attempt survivors to prevent reattempts. These approaches typically focus on coping and other emotional regulation skills and may include **case management home visits to increase adherence to and continuity of care**, one-on-one interpersonal therapy and/or group therapy. Approaches that engage and connect attempters to peers and providers are especially important because many attempters do not present to aftercare; 12%-25% reattempt within a year, and 3%-9% of attempt survivors die by suicide within 1 to 5 years of their initial attempt (Inagaki, et al., 2015).
- **Postvention** approaches are implemented after a suicide has taken place and may include debriefing of survivors (those who have lost a friend, peer, family member, co-worker to suicide), counseling, and/or bereavement support groups. The programs have not typically tested their impact on suicide or suicidal behavior but may reduce risk of guilt, feelings of depression, and complicated grief (Szumilas et al., 2011). Additionally, research suggests that active postvention approaches in which outreach to suicide survivors occurs at the scene of a suicide is associated with intake into treatment sooner, greater attendance at support group meetings, and attendance at more meetings compared to passive postvention (no outreach) (Cerel & Campbell, 2008).

- **Safe messaging following a suicide.** The manner in which information on a recent suicide is communicated to the public (e.g. school assemblies, mass media, social media) can heighten the risk of suicide among vulnerable individuals and can inadvertently contribute to suicide contagion.

## Potential Outcomes

- Reduction in mental health-related sequelae
- Increase connectedness
- Improved coping skills
- Improved messaging following suicide
- Reduction in re-attempts

## Evidence

The evidence addressing strategies to lesson harm and prevent future risk of suicide includes the evaluation of effects of specific approaches on risk and protective factors as well as suicide-related mortality. However, because the evaluation of suicide-related mortality is a statistically rare event, evaluation of mortality outcomes requires large sample sizes and extended follow-up. Therefore, much of the evidence in this area primarily focuses on risk and protective factors.

- **Treatment for people at-risk of suicide.**

Psychotherapy has been demonstrated to help diverse individuals in different settings to reduce risks related to mental health problems such as depression and anxiety, and to reduce suicidal ideation and attempts. Evaluation evidence for selected psychotherapeutic approaches to prevent future suicide risk follow below.

**Improving Mood – Promoting Access to Collaborative Treatment (IMPACT)** aims to prevent suicide among older primary care patients by reducing suicide ideation and depression in primary care settings. IMPACT facilitates the development of a therapeutic alliance, a personalized treatment plan that includes patient preferences, as well as proactive follow-up (biweekly during an acute phase and monthly during continuation phase) by a depression care manager. IMPACT has been shown to significantly improve quality of life, and to reduce functional impairment, depression (Hunkeler et al., 2006; Unützer et al., 2002) and suicidal ideation over 24-months of follow-up (Unützer et al., 2006) relative to patients who received care as usual.

**Collaborative Assessment and Management of Suicidality (CAMS)** is a therapeutic framework for suicide-specific assessment and treatment of patient's suicide risk. It is a flexible approach that can be used across treatment settings and clinician theoretical orientations. The clinician and patient work together in an interactive assessment process. The patient is highly engaged in the development of their own treatment plan. Every session of CAMS is collaborative and involves the patient's input about what is and is not working. Ultimately, this process is designed to enhance the therapeutic alliance and increase treatment motivation in the suicidal patient. CAMS has been tested and supported in 6 correlational studies (Jobes, 2012), in a variety of inpatient and outpatient settings and in one RCT with several additional RCTs under way. CAMS has been associated with significant improvements in suicidal ideation, overall symptom distress, and feelings of hopelessness at 12 month follow-up among a community-based sample of suicidal outpatients. (Comtois et al., 2011).

**Dialectical Behavioral Therapy** is a multicomponent therapy for individuals at high risk for suicide who may struggle with impulsivity and emotional regulation. The components of DBT include individual therapy, group skills training, between-session telephone coaching and a therapist consultation team. In a randomized controlled trial of women with recent suicidal or self-injurious behavior, those receiving DBT were half as likely to make a suicide attempt at two-year follow-up than women receiving community treatment (23% vs 46%), required less hospitalization for suicide ideation, and had lower medical risk across all suicide attempts and self-injurious acts combined (Linehan et al., 2006).

**Attachment-Based Family Therapy (ABFT)** is a program for adolescents ages 12-18 that is designed to treat clinically diagnosed major depressive disorder, eliminate suicidal ideation, and reduce dispositional anxiety. A randomized controlled trial of ABFT (Diamond et al., 2010) found that suicidal adolescents assigned to ABFT experienced significantly greater improvement regarding suicidal ideation over 24 weeks of follow-up than did adolescents assigned to enhanced usual care (-4.37 vs. -2.34;  $p = .001$ ;  $d=0.97$ ). A higher percentage of ABFT participants reported no suicidal ideation in the past week at 12 weeks than did adolescents receiving enhanced usual care (69.2% vs. 34.6%;  $p = .01$ ; OR= 4.25) and at 24 weeks (82.1% vs. 46.2%;  $p = .006$ ; OR=5.37).

- **Treatment to prevent re-attempts.**

Active contact and follow-up approaches intended to prevent reattempts among patients that have been hospitalized and subsequently discharged for suicide attempts have been found in a meta-analysis conducted by Inagaki et al., (2015) to reduce reattempts by approximately 17% for up to 12 months post-discharge, however, the long-term effects of these approaches on reattempts has not yet been demonstrated. Also, because the number of trials and associated sample sizes included in this meta-analysis were small, it was not possible to determine the effect

of active contact and follow-up approaches on death by suicide. In a randomized controlled trial of postcrisis suicide prevention long-term follow-up contact approach, Motto et al., (2001) found that patients who refused ongoing care but who were randomized to be contacted by letter four times per year had a lower rate of suicide over two years of follow-up than did patients in the control group who received no further contact. Other studies have also shown post-crisis letters and coping cards to be protective against suicide ideation and attempts (Hassanian-Moghaddam et al., 2011; Wang et al., 2016).

- **Postvention** approaches such as *StandBy Response Service* provide suicide bereavement support services to clients via face-to-face outreach and telephone support delivered by a professional crisis response team. A site coordinator develops a customized case management plan, referring clients to other existing community services matched to their needs. In a study by Visser et al. (2014), *StandBy* clients were significantly less likely to be at high risk for suicidality than a suicide bereaved comparison group who had not had contact with the *StandBy* program (48% and 64% respectively,  $p = 0.005$ ).
- **Safe messaging following a suicide.** *Media* guidelines for reporting on suicides can help assure that stories on suicide are communicated in a safe and effective way. Reports that are both inclusive of suicide prevention messages, stories of hope and resilience, risk and protective factors, and links to helping resources (e.g., hotline) and that avoid sensationalizing events or reducing suicide to one cause can help reduce the likelihood of suicide contagion. The most compelling evidence supporting the effect of media guidelines on reduction in suicides comes from Austria. After a sharp increase in suicides on the Viennese subway, media guidelines were introduced and an interrupted time series design was used to evaluate the national impact of the guidelines on subsequent suicides. Changes in the quality and quantity of media reporting resulted in a reduction of 81 suicides annually (95% confidence interval: -149 to -13;  $t = -2.32$ ,  $df = 54$ ,  $p < 0.024$ ) in the Viennese subway system (Niederkrötenhaller, T., & Sonneck, G., 2007)

## Sector Involvement

Public health can play an important and unique role in addressing suicide. Public health agencies, which typically place prevention at the forefront of efforts and work to create broad population-level impact, can bring critical leadership and resources to bear on this problem. For example, these agencies can serve as a convener, bringing together partners and stakeholders to plan, prioritize, and coordinate suicide prevention efforts. Public health agencies are also well positioned to collect and disseminate data, implement preventive measures, evaluate programs, and track progress. Although public health can play a leadership role in preventing suicide, the strategies and approaches outlined in this technical package cannot be accomplished by the public health sector alone.

Other sectors vital to implementing this package include, but are not limited to, education, government (local, state, and federal), social services, health services, business/labor, justice, housing, media, and organizations that comprise the civil society sector such as faith-based organizations, youth-serving organizations, foundations, and other non-governmental organizations. Collectively, these sectors can

make a difference in preventing suicide by impacting the various contexts and underlying risks that contribute to suicide.

The strategies and approaches described in this technical package are summarized in Appendix A along with the relevant sectors that are well positioned to lead implementation efforts.

[I can write the text specific to the strategies and approaches. I've done this for the other TPs and am happy to do the same here. This is the section where we distinguish the strategies where public health is best positioned to lead from those where leadership is necessary from other sectors and how public health can assist, etc.]

Regardless of strategy, action by many sectors will be necessary for the successful implementation of this package. In this regard, all sectors can play an important and influential role in.....

## Monitoring and Evaluation

Monitoring and evaluation are necessary components of the public health approach to prevention. It is important to have timely and reliable data to monitor the extent of the problem and to evaluate the impact of prevention efforts. Data are necessary for program implementation; planning, implementation, and assessment all rely on accurate measurement of the problem.

Surveillance data helps researchers and practitioners track changes in the burden of suicide. Surveillance systems exist at the federal, state, and local levels. It is important to assess the availability of surveillance data and data systems across these levels to identify and address gaps in the systems. CDC's National Vital Statistics System and the National Violent Death Reporting System (NVDRS) are examples of surveillance systems that provide data on deaths from suicide. NVDRS, for example, is a state-based surveillance system that combines data from death certificates, law enforcement reports, and coroner or medical examiner reports to provide detailed information on the circumstances of violent deaths, including suicide, which can assist communities in guiding prevention approaches (Blair et al., 2016). The National Electronic Injury Surveillance System-All Injury Program (NEISS-AIP) provides nationally representative data about all types and causes of nonfatal injuries treated in U.S. hospital emergency departments, and can be used to assess national rates of, and trends in, self-harm injuries by cause (e.g., falls, poisoning, etc.), age, race/ethnicity, sex, disposition (where the injured person goes when released from the Emergency Department (<http://www.cdc.gov/injury/wisqars/nonfatal.html>)).

In addition to information on deaths and nonfatal injuries, there are also surveillance systems that provide national, state, and some local estimates of suicidal behavior. The Youth Risk Behavior Surveillance System (YRBSS) collects information from a nationally representative sample of 9-12 grade students and is a key resource in monitoring health-risk behaviors among youth, including whether youth have seriously considered attempting suicide, attempted suicide, made a plan, or required treatment by a doctor or nurse for a suicide attempt that resulted in an injury, poisoning, or overdose (Brener et al., 2013). The YRBSS data are obtained from a national school-based survey conducted by CDC as well as school-based state, territorial, tribal, and large urban school district survey conducted by education and health agencies. The National Survey on Drug Use and Health (NSDUH) is an annual nationwide survey of individuals aged 12 years and older that provides national and state-level estimates of drug use and mental health-related issues, including suicide ideation and suicide attempts (<https://nsduhweb.rti.org/respweb/homepage.cfm>).

It is also important at all levels (local, state, and federal) to address gaps in responses, track progress of prevention efforts and evaluate the impact of those efforts, including the impact of this technical package. Evaluation data, produced through program implementation and monitoring, is essential to provide information on what does and does not work to reduce rates of suicide and its associated risk and protective factors. Theories of change and logic models that identify short, intermediate, and long-term outcomes are an important part of program evaluation.

The evidence-base for suicide prevention has advanced greatly over the last few decades. However, additional research is needed to..... Lastly, it will be important for researchers to test the effectiveness of combinations of the strategies and approaches included in this package. Most existing evaluations focus on approaches implemented in isolation. However, there is potential to understand the synergistic effects within a comprehensive prevention approach. Additional research is needed to understand the extent to which combinations of strategies and approaches result in greater reductions in suicide than individual programs, practices, or policies.

**Comment [A]:** I'll help you complete the lead sector column. For the other columns, you just need to insert a check-mark based on the evidence you describe in the narrative for a particular program or policy. For example, if the evidence shows impact on suicide, then put a check-mark in that column. If the study also found effects on risk or protective factors, then put a check-mark in that column as well.

## Overview

This technical package represents a select group of strategies based on the best available evidence to help communities and states sharpen their focus on prevention activities with the greatest potential to prevent suicide. Broadly, the strategies represented include those with a focus on preventing suicide from happening in the first place as well as approaches to lessen the immediate and long-term effects of suicidal behavior for individuals, families, communities, and society. Specifically, the strategies include strengthening economic supports; strengthening access to mental health care; establishing protective environments; promoting connectedness to protect against suicide; teaching coping and problem-solving skills; identifying and supporting people at-risk; and intervening to lessen harms and prevent future risk.

This package supports the National Strategy for Suicide prevention, Goal 1, "Integrate and coordinate suicide prevention activities across multiple sectors and settings." (p.29) It also supports the National Action Alliance for Suicide Prevention's priority "To create and disseminate a framework for comprehensive community-based suicide prevention." (<http://actionallianceforsuicideprevention.org/priorities>)

Commitment, cooperation, and leadership from numerous sectors, including public health, education, justice, health care, social services, business/labor, and government can bring about the successful implementation of this package.

### What is a Technical Package?

A technical package is a compilation of a core set of strategies to achieve and sustain substantial reductions in a specific risk factor or outcome (Frieden, 2014). Technical packages help communities and states prioritize prevention activities based on the best available evidence. This technical package has three components. The first component is the **strategy** or the preventive direction or actions to achieve the goal of preventing suicide. The second component is the **approach**. The approach includes the specific ways to advance the strategy. This can be accomplished through *programs, policies, and practices*. The approaches included come primarily from studies based in the United States. The evidence for each of the approaches in preventing suicide or its associated risk factors is included as the third component. This package is intended as a resource to guide and inform prevention decision-making in communities and states.

### Preventing Suicide is a Priority

Suicide, as defined by the CDC, is part of a broader class of behavior called *self-directed violence*. Self-directed violence refers to behavior directed at oneself that deliberately results in injury or the potential for injury (1). Self-directed violence may be *suicidal* or *non-suicidal* in nature. For the purposes of this document, we refer only to behavior where suicide is intended.

Comment [A]: Changed the word "harms" here to effects since we use harms in the next sentence.

Comment [A]: New sentences

Comment [A]: New sentence

- **Suicide** is a death caused by self-directed injurious behavior with any intent to die as a result of the behavior.
- **Suicide attempt** is defined as a *non-fatal* self-directed and potentially injurious behavior with any intent to die as a result of the behavior. A suicide attempt may or may not result in injury.

### **Suicide is highly prevalent.**

Suicidal behavior presents a major challenge to public health in the United States and worldwide. It contributes to premature death, morbidity, lost productivity, and health care costs (2, 3). In 2014 in the U.S., the most recent death data available, suicide was responsible for 42,773 deaths, which is approximately a suicide every 12 minutes (4). In 2014, suicide ranked as the tenth leading cause of death and has been among the top twelve leading causes of death since 1975 in the U.S. (5) Overall suicide rates have increased from 1999 to 2014 (24% increase) (6). Suicide is a problem throughout the life span; it is the second leading cause of death among those aged 10–19 years, also second among persons in their 20s and 30s; it is the fourth leading cause among persons in their 40s and seventh among persons in their 50s (4).

Suicides reflect only a portion of the number of persons affected by suicidal thoughts and behaviors (7). Substantially more persons are hospitalized as a result of nonfatal suicidal behaviors than are fatally injured, and an even greater number are either treated in ambulatory settings or not treated at all (7). For example, during 2014, among adults aged  $\geq 18$  years, for every one suicide there were 9 adults treated in hospital emergency departments for self-inflicted injuries, 27 who reported making a suicide attempt, and over 227 who reported seriously considering suicide (8). Suicides, attempts, and ideation take an immense emotional, physical, and economic toll on individuals, families and communities. By one estimate, for every death by suicide six people are directly impacted (i.e. survivors). Based on this figure it is estimated that there are over 13 million survivors in the U.S. and unfortunately, survivorship itself is a risk factor for suicide (9).

**Suicide is associated with several risk and protective factors.** Suicide, like other human behaviors, is complex with no single determining cause. It occurs in response to multiple biological, psychological, interpersonal, environmental and societal influences that interact with one another and act cumulatively to increase one's vulnerability to think about or engage in suicidal behaviors. The social-ecological model is a useful framework for viewing and understanding suicidal risk factors that have been identified in the literature<sup>1</sup>:

#### Risk Factors for Suicide<sup>2,3</sup>

- ❑ **Individual:** History of depression and other mental illnesses, alcohol and drug abuse, previous suicide attempt, previous victimization, acute and chronic stressors (e.g. financial problems), genetic and biological determinants, hopelessness
- ❑ **Relationship:** High conflict or violent relationships, sense of isolation and lack of social support, family history of suicide, financial and work stress
- ❑ **Community:** Inadequate community connectedness, barriers to health care-- lack of access to providers or medications
- ❑ **Societal:** Availability of lethal means of suicide, unsafe media portrayals of suicide, stigma associated with help-seeking

An individual having or experiencing one or a number of risk factors does not always lead to suicide; for example, the vast majority of individuals who are depressed do not die by suicide. It is also important to note that these risk factors described above is not an exhaustive list. These and many other risk factors exist and can be arranged differently or contribute to multiple areas within the social-ecological model. Furthermore, the relevance of each risk factor can vary by age, race, gender, sexual orientation, residential geography, and socio-cultural and economic status<sup>2,3</sup>.

Protective factors for suicide: Protective factors, or those influences that guard against the risk for suicide, can also be found across the different levels of the social-ecological model and may vary in significance depending on the context in which the suicide occurs. Protective factors identified in the literature include: effective coping and problem solving skills, moral objections to suicide, strong and supportive relationships with partners, peers, and family, connectedness to school, community and other social institutions and the availability of physical and mental health care<sup>2,3</sup>. These protective factors can either counter a specific risk factor or guard against a number of risks associated with suicide.

### **Suicide is connected to other forms of violence.**

Suicide is connected to other forms of violence in a number of different ways. First, suicide and other forms of violence often share some of the same root causes. They can all take place under one roof, or in a given community or neighborhood and can happen at the same time or at different stages of life.<sup>1,2</sup> For example, in neighborhoods where there is low cohesion, or where residents don't support and trust each other, people are at higher risk for suicide<sup>3</sup> as well as perpetration of child maltreatment,<sup>4,5</sup> teen dating violence,<sup>6</sup> intimate partner violence,<sup>7</sup> and youth violence.<sup>8</sup> Lack of economic opportunities and unemployment are associated with suicide,<sup>9,10</sup> as well as perpetration of child maltreatment,<sup>11</sup> intimate partner violence,<sup>12,13</sup> sexual violence<sup>14</sup> and youth violence.<sup>15</sup> Also, while most people who are victims of violence do not act violently or die by suicide, people who experience or are exposed to suicide are at a higher risk for both being a victim of other forms of violence and for inflicting harm on others. For example, children who experience physical abuse or neglect early in their lives are at greater risk for suicide,<sup>16</sup> and also at greater risk for committing violence against peers (particularly for boys),<sup>17</sup> bullying,<sup>18</sup> teen dating violence,<sup>19</sup> and committing child abuse,<sup>20</sup> elder abuse,<sup>21</sup> intimate partner violence,<sup>22</sup> and sexual violence<sup>23</sup> later in life. There are also a number of protective factors that pose an opportunity to protect individuals and communities from suicide and other forms of violence, and buffer the effects of shared risk factors. For example, connectedness increases peoples' and communities' resilience to suicide and other forms of violence, including connectedness to one's community,<sup>24,25,26,27,28,29,30</sup> school,<sup>31,32,33,34,35,36</sup> family,<sup>37,38,39,40,41</sup> caring adults,<sup>42,43,44</sup> and pro-social peers.<sup>45,46</sup>

### **The health and economic consequences of suicide are substantial.**

Total lifetime costs associated with nonfatal injuries and deaths caused by self-directed violence in 2013 were approximately \$93.5 billion after adjusting for under-reporting of suicide (10).

### **Suicide can be prevented.**

Despite the myths surrounding suicide, like most public health problems, suicide is preventable. And while progress will continue to be made into the future, evidence for numerous programs, practices, and policies currently exist and are ready to be implemented now. Just as suicide is not caused by a single factor, research suggests that suicide will not be prevented by any single intervention taking place in any single setting. Rather, suicide prevention is best achieved by a focus across the individual-, relationship-, family-, community, and societal-levels and across all sectors, private and public (e.g., business, public health, physical and behavioral healthcare, justice, education, labor). According to CDC Director, Tom Frieden, successful public health programs also require political commitment, funding, communication, and performance monitoring.

## **Assessing the Evidence**

This technical package includes programs, practices, and policies with evidence of impact on suicide or risk or protective factors for suicide. To be considered for inclusion in the technical package, the program, practice, or policy selected had to meet at least one of these criteria: a) meta-analyses or systematic reviews showing impact on suicide; b) evidence from at least one rigorous (e.g., randomized controlled trial [RCT] or quasi-experimental design) evaluation study that found significant preventive effects on suicide; c) meta-analyses or systematic reviews showing impact on risk or protective factors for suicide, or d) evidence from at least one rigorous (e.g., RCT or quasi-experimental design) evaluation study that found significant impacts on risk or protective factors for suicide. Finally, consideration was also given to the likelihood of achieving beneficial effects on multiple forms of violence; no evidence of harmful effects on specific outcomes or with particular subgroups; and feasibility of implementation in a U.S. context if the program, policy, or practice has been evaluated in another country.

Within this technical package, some approaches do not yet have research evidence demonstrating impact on rates of suicide but instead are supported by evidence indicating impacts on risk or protective factors for suicide (e.g., help-seeking, stigma reduction, depression, connectedness). In terms of the strength of the evidence, programs that have demonstrated effects on suicidal behavior (e.g., reductions in deaths, attempts) provide a higher-level of evidence, but the evidence base is not that strong in all areas. For instance, there has been less evaluation of community engagement and family programs on suicidal behavior. Thus, approaches in this package that have effects on risk or protective factors reflect the developmental nature of the evidence base and the use of the best available evidence at a given time.

It is also important to note that there is often significant heterogeneity among the programs, policies, or practices that fall within one approach or strategy area in terms of the nature and quality of the available evidence. Not all programs, policies, or practices that utilize the same approach (e.g., gatekeeper training) are equally effective, and even those that are effective may not work across all populations. Tailoring programs and more evaluation may be necessary to address different population groups. The examples provided are not intended to be a comprehensive list of evidence-based programs, policies, or practices for each approach, but rather illustrate models that have been shown to impact suicide or have beneficial effects on risk or protective factors for suicide. In practice, the effectiveness of the programs, policies and practices identified in this package will be strongly dependent on the quality of their implementation and the communities in which they are implemented. Implementation guidance to assist practitioners, organizations and communities will be developed separately.

### **Context and Cross-Cutting Themes**

The strategies and approaches that have been included in this technical package represent different levels of the social ecology, with efforts intended to impact the community and societal levels, as well individual and relationship levels. The strategies and approaches are intended to work in combination and reinforce each other to prevent suicide (see box below). The strategies are arranged in order such

that those strategies hypothesized to have the greatest potential for broad public health impact on suicide are included first, followed by those that might impact more select populations (e.g., persons who have already made a suicide attempt).

Preventing Suicide	
Strategy	Approach
Strengthen economic supports	<ul style="list-style-type: none"> <li>Strengthen financial security</li> <li>Housing stabilization policies</li> </ul>
Strengthen access to mental health care	<ul style="list-style-type: none"> <li>Coverage of mental health conditions in health insurance policies</li> </ul>
Establish protective environments	<ul style="list-style-type: none"> <li>Means restriction</li> <li>Organizational policies and culture</li> <li>Community-based policies to reduce excessive alcohol use</li> </ul>
Promote connectedness to protect against suicide	<ul style="list-style-type: none"> <li>Peer norm approaches</li> <li>Community engagement activities</li> </ul>
Teach coping and problem-solving skills	<ul style="list-style-type: none"> <li>Social-emotional learning</li> <li>Parenting skill and family relationship approaches</li> </ul>
Identify and support people at risk	<ul style="list-style-type: none"> <li>Gatekeeper training</li> <li>Screening combined with care management</li> <li>Crisis intervention</li> </ul>
Intervene to lessen harms and prevent future risk	<ul style="list-style-type: none"> <li>Treatment for people at-risk of suicide</li> <li>Treatment to prevent re-attempts</li> <li>Postvention</li> <li>Safe messaging following a suicide</li> </ul>

The example programs, policies, and practices have been implemented within particular contexts. The social and cultural context of communities is critically important to take into account when selecting strategies and approaches. Practitioners in the field may be in the best position to assess the needs and strengths of their communities and work with community members to make decisions about the combination of approaches included here that are best suited to their context.

[Add text for other issues to potentially cover in this section. You may want to take a look at the other packages in this regard]

This package includes strategies where public health agencies are well positioned to bring leadership and resources to implementation efforts. It also includes strategies where public health can serve as an important collaborator (e.g., strategies addressing community and societal level risks), but where leadership and commitment from other sectors such as business/labor or health care is critical to implement a particular policy or program (e.g., workplace policies; screening combined with care management). The role of various sectors in the implementation of a strategy or approach in preventing suicide is described further in the section on *Sector Involvement*.

In the sections that follow, the strategies and approaches with the best available evidence for preventing suicide are described.

## Strengthen Economic Supports

### Rationale

### Approaches

Brief statement introducing the approaches (see example statements in the other technical packages).

- **Strengthen household financial security.** Research indicates that economic crises are related to suicide rates. Findings from the U.S. show that suicide rates increase during economic recessions marked by high unemployment rates, job losses, and economic instability and decrease during economic expansions and periods marked by low unemployment rates, particularly for working-age individuals 25 to 64 years old (Luo et al., 2011; Fowler et al., 2015). Policies that support financial security during difficult economic times have been shown to mitigate the risk of economic crises on suicide rates.
- **Housing stabilization policies** that aim to strengthen housing stability and security may help to buffer the impact of foreclosures and evictions on suicide, as recent research has drawn an association between housing instability and suicidal behavior. Programs that provide affordable housing and other options for homebuyers such as loan modification programs may be used in conjunction with move-out planning and financial counseling services to minimize the impact of foreclosures and evictions on suicide.

### Potential Outcomes

- 
- 
- 

### Evidence

Brief statement introducing the evidence [see example statements in the other technical packages].

- **Strengthen household financial security.**

- **Housing stabilization policies.**

## Strengthen Access to Mental Health Care

### Rationale

Mental illness is a risk factor for suicide. Studies suggest that up to 90% of people who die by suicide may have had a mental illness (Cavanaugh et al., 2003). Research on state-level suicide rates have been found to be correlated with general mental health measures such as depression (Arsenault-Lapierre, et al., 2004). While most people with mental health problems do not attempt or die by suicide, assuring access to quality mental health care is critical to suicide prevention.

### Approaches

A major approach to strengthening access to mental health care is to have health insurance policies that include coverage for such services.

- **Coverage of mental health conditions in health insurance policies.** Health insurance policies that allow people with mental health problems to access mental health treatment in the same way that they access health care for physical health concerns can increase use of mental health services, help normalize treatment seeking in the population, reduce symptoms of mental illnesses like depression and bipolar disorder, and in turn, reduce rates of suicide and suicide attempts.

### Potential Outcomes

- Increased access to mental health services
- Decreased symptoms of mental illnesses
- Decreased rates of suicide attempts
- Decreased rates of suicide

### Evidence

Brief statement introducing the evidence.

- **Coverage of mental health conditions in health insurance policies.**  
Using data from the National Survey of Drug Use and Health, Harris et al. (2006) found that 12 months after states enacted parity laws, self-reported use of mental healthcare services significantly increased. Subsequent research by Lang et al. (2011), suggests that mental health parity laws are associated with an approximate 5% reduction in suicide rates. This reduction (in 29 states) equated to the prevention of 592 suicides per year and a cost savings of \$1.3-3.1 million per suicide prevented (Lang, 2013).

## Establish Protective Environments

### Rationale

Suicide prevention efforts that focus on *both* the individual *and* his/her environment increase the likelihood of lives saved. Establishing protective environments helps ensure that all of the places where an individual lives, works, and plays are supportive. Limiting access to lethal means, be it at home or in nature, and particularly when an individual may be most vulnerable, can literally make the difference between life and death. Likewise, creating a work environment conducive to prevention and focused on employee well-being supports the large majority of the population where they spend much of their day. Finally, policies that reduce the availability of alcohol, a potent suicide risk factor, serve to support individuals and protect the environment further.

### Approaches

The current evidence suggests three approaches with promise for creating environments that protect against suicide. These include:

- **Means Restriction.** Modifying the environment to decrease access to lethal means is an important public health strategy for preventing suicide. Acute suicidal crises are often brief and impulsive. Previous research indicates that the interval between thinking about suicide and attempting can be as short as 5-10 minutes (Simon et al., 2001; Deisenhammer et al., 2009). Getting past the impulse by making it more difficult to access lethal means can be lifesaving. Highly lethal means such as firearms, hanging/suffocation, or jumping from heights provide little opportunity for rescue and have high fatality rates (e.g., about 85% of people who use a firearm in an attempt die from their injury). Research also indicates that most people tend not to substitute a different method when a highly lethal method is unavailable or difficult to access (Hawton, 2007; Yip et al., 2012). Removing or restricting access to lethal means changes the context of the potential suicide and whether the outcome will be fatal or non-fatal (Yip et al., 2012).
  - *Intervening at Suicide Hotspots.* These interventions are focused on preventing suicides at locations which offer direct means for suicide or a secluded place that prevents intervention. Suicide hotspots include tall structures (for example, bridges and cliffs), railway tracks, and isolated locations that are popular destinations for suicide (for example, parks). Interventions include barriers to prevent jumping and signs and telephones to encourage suicidal individuals to seek help.
  - *Safe Storage Practices* for medications, firearms, and other household products can reduce the risk for suicide by preventing impulsive action and separating individuals from easy access to lethal means. Safe storage practices include education and counseling around storing firearms locked in a secure place (e.g., in a gun safe or lock box), preferably unloaded and separate from the ammunition. Keeping medicines in a

locked cabinet or secure location can also prevent their misuse by children and adolescents.

- **Organizational policies and culture** that focus on prosocial behavior, skill building, changing social norms, referral and access to helping services (e.g. mental health, substance abuse treatment, financial counseling), and that have leadership support from the top down can positively impact organizational climate and morale and help prevent suicide and its related risk factors (e.g. depression, social isolation).
- **Community-based policies to reduce excessive alcohol use.** Acute alcohol use has been found to be associated with more than one-third of suicides and approximately 40% of suicide attempts (Cherpitel, Borges & Wilcox, 2004). While various community policies exist to reduce excessive alcohol use (e.g., zoning limits related to alcohol outlet locations and density, taxes on alcohol, and bans on the sale of alcohol for individuals under the legal drinking age), previous research indicates that policies related to outlet locations and density are more strongly associated with suicide, making these particular policies an important approach to preventing suicide.

### Potential Outcomes

- Increase in safe storage of lethal means
- Reduction in suicide attempts
- Reduction in suicide deaths
- Reduction in alcohol-related suicide deaths

### Evidence

The evidence for the effectiveness of means restriction and other ways to establish protective environments is some of the strongest in the field (Zalsman et al., 2016).

- **Means restriction**
  - *Intervening at suicide hotspots* A meta-analysis of suicide hotspot interventions implemented in combination or in isolation in the U.S. and abroad found they reduced suicide (Pirkis et al., 2015; Cox, 2013). For example, suicide deaths from jumping from the Jacques-Cartier bridge in Canada decreased after the installation of a bridge barrier (incidence rate ratio [IRR] = 0.24; 95% confidence interval [CI] = 0.13, 0.43), which persisted when all bridges (IRR = 0.39; 95% CI = 0.27, 0.55) and all jumping sites (IRR = 0.66; 95% CI = 0.54, 0.80) in the regions were considered, suggesting little or no displacement to other jumping sites (Perron, et. al., 2013). In contrast, the

removal of safety barriers on the Grafton Bridge in Auckland, New Zealand led to an immediate and substantial increase in both the numbers and rate of suicide by jumping from the bridge from 3 to 15 ( $p < 0.01$ ); the rate of such deaths also increased ( $p < 0.01$ ; Beautrais, 2001; Beautrais, et. al., 2009).

- *Safe storage practices* In a case-control study of firearm-related events identified by medical examiner and coroner offices from 37 counties in Washington, Oregon, and Missouri, and 5 trauma centers, Grossman et al., (2005) found that safe storage practices (i.e., storing firearms unloaded, separate from ammunition, in a locked place and/or secured with a safety device) were protective for suicide attempts among adolescents (Grossman et al., 2005). A recent systematic review of clinic and community-based education and counseling around safe storage of firearms found that the provision of safety devices significantly increases safe firearm storage practices compared to counseling alone or providing economic incentives to acquire safety devices (Rowhani-Rahbar, Simonetti, & Rivara, 2016). The *Emergency Department Counseling on Access to Lethal Means (ED CALM)* program trained psychiatric emergency clinicians in a large children's hospital to provide lethal means counseling and safe storage boxes to parents of patients under age 18 receiving care for suicidal behavior. In a pre-post study, Runyan et al (2015) found that among the parents contacted at follow-up, 76% reported all medications in the home were locked up as compared to fewer than 10% at the time of the initial emergency department visit. Among parents who indicated the presence of guns in the home at the time of the child's initial emergency department visit, all reported guns were currently locked, compared to 67% reporting this at the time of the initial visit.
- **Organizational policies and culture** *Together for Life* is a workplace program of the Montreal Police Force implemented to address suicide among officers. Policy and program components of *Together for Life* were designed to foster an organizational culture that promoted mutual support and solidarity among members of the Force, help for problems related to suicide, training of supervisors, managers and all units to improve competencies in identifying suicidal risk and in using existing resources, and an education campaign to improve awareness and help-seeking. After implementation of the program, police suicides were tracked over 12 years and compared to rates in the control city of Quebec. Pre-post assessments of learning, interviews, and focus groups were also included. The suicide rate in the intervention group decreased significantly by 78.9% ( $p < .008$ ) to 6.42 per 100,000 per year compared to 29.0 per 100,000 in the control city--a significant difference in rates ( $p < .007$ ) (Mishara & Martin, 2012).

*The United States Air Force Suicide Prevention Program (AFSPP)*, inclusive of 11 policy and education initiatives, was designed to change the culture of the Air Force surrounding suicide. The program uses leaders as role models and agents of change, establishes expectations for behavior related to awareness of suicide risk, develops population skills and knowledge (i.e., education and training), and investigates every suicide (i.e., outcomes measurement). The program represents a fundamental shift from viewing suicide and mental illness solely as medical problem and instead sees them as larger service-wide problems impacting the whole community. Using a time-series design, the *AFSPP* program

was associated with a 33% relative risk reduction in suicide (Knox et al., 2003). The program was also associated with relative risk reductions in related outcomes including moderate and severe family violence (30% and 54%, respectively), homicide (51%), and accidental death (18%); Knox et al., 2003). A longitudinal assessment of the program over the period 1981 to 2008 (16 years before the 1997 launch of the program and 11 years post-launch) found significantly lower rates of suicide after the program was launched than before (Knox et al., 2010). These effects were sustained over time, except in 2004, which the authors found was associated with less rigorous implementation in that year than in the other years (Knox et al., 2010).

- **Community-based policies to reduce excessive alcohol use** Several studies on alcohol outlet density in the United States have found that greater alcohol availability is positively associated with alcohol-involved suicides (Giesbrecht et al., 2014; Escobedo & Ortiz, 2002). For example, Giesbrecht et al. (2014) found that both on and off-premises alcohol outlets (i.e., restaurants where alcohol is served and stores where alcohol is available for purchase to go) were positively associated with alcohol-related suicides in 14 U.S. states, particularly among men (AOR 1.08, CI=1.03-1.13) and American Indian/Alaska Natives (AOR= 1.36; CI= 1/10-1.69). Additionally, a longitudinal analysis of alcohol outlet density, suicide mortality, and hospitalizations for suicide attempts over 6 years in 581 California zip codes indicated that the density of bars, specifically, is related to suicide and suicide attempts, particularly in rural areas (Johnson, Gruenewald & Remer, 2009). These findings suggest that measures to reduce alcohol outlet density can potentially reduce alcohol-involved suicides.

## Promote Connectedness to Protect Against Suicide

### Rationale

The quantity and quality of our social connection with others has been linked with suicide dating as far back to Durkheim, who first posited that the weakening social bonds is among the chief causes for suicidality<sup>1</sup>. Connectedness is the degree to which an individual or group of individuals are socially close, interrelated, or share resources with others<sup>2</sup>. Connectedness can be formed within and between multiple levels of the social ecology<sup>3</sup>; for instance between individuals (e.g. peers, neighbors, co-workers), families, schools, neighborhoods, workplace, faith communities, cultural groups, and society as a whole. Connectedness is also viewed as a broad term that encompasses several other concepts including social support, social participation, social isolation, social cohesion, social capital, social integration, all of which have been linked to suicidal behaviors either conceptually or scientifically within the literature. Connectedness can serve either to protect or mitigate suicidal behaviors by decreasing isolation, encouraging adaptive coping behaviors, increasing belongingness, personal value and worth all of which helps individuals to build resilience in the face of adversity. Connectedness can also provide individuals with better access to formal supports and resources, mobilize communities to meet the needs of its members and provide collective primary prevention activities to the community as a whole<sup>2</sup>.

[insert info on connectedness and include some or all of the following re social capital here]. Social capital refers to a sense of trust in one's community and neighborhood, social integration, and also the availability and participation in social organizations (Muenning et al., 2013; Beyer et al., 2014). Many ecological cross-sectional and longitudinal studies have examined the impact of aspects of social capital on depression symptoms, depressive disorder, mental health more generally, and suicide. While the evidence is still being built the pattern is towards an inverse association between social capital measured by social trust, community/neighborhood engagement, and improved mental health

### Approaches

The following two approaches are designed to promote connectedness among individuals and within communities to protect against suicide.

- **Peer norm approaches** seek to normalize help-seeking, encourage reaching out and talking to trusted adults, and promote supporting peers through building connectedness. These approaches are typically delivered in school settings but can also be implemented in community settings.

**Comment [A]:** This is what was in the table that Linda said could be added to the rationale.

- **Community engagement activities.** Community engagement is an aspect of social capital and involves residents participating in a range of activities, including religious activities, community clean-up and greening activities, and physical exercise. These activities provide opportunities for residents to become more involved in the community and to connect with other community members, organizations, and resources, resulting in enhanced overall physical health, reduced stress, and decreased depressive symptoms, thereby reducing risk of suicide.

### Potential Outcomes

- Reduction in maladaptive coping attitudes and behaviors
- Increase in healthy coping attitudes and behaviors
- Increase in referrals for youth in distressed
- Increase help-seeking behaviors
- Positive perception of adult support

### Evidence

Brief statement to introduce the evidence.

Current evidence provide some support for these types of approaches for reducing risk factors associated with suicidal behaviors.

- **Peer norm approaches.** Evaluations show that programs such as *Sources of Strength (SOS)* can improve school norms and beliefs about suicide that are created and disseminated by student peers. In a randomized controlled trial of the program conducted with 18 urban and rural high-schools Wyman et al., (2010)<sup>4</sup> found that *SOS* improved peer leaders' knowledge of adult supports for suicidal peers ( $p<.01$ ) and were more likely than untrained leaders to refer distressed peers to adult supports ( $p<.03$ ). Trained peer leaders also reported a greater decrease in maladaptive coping attitudes compared with untrained leaders ( $p<.01$ ).
- **Community-engagement activities.** *Greening vacant urban spaces* is an initiative that communities have adopted, particularly after the Great Recession (2007-2009) when many cities across the U.S. experienced urban abandonment. These initiatives engaged community members in the cleaning, greening, or beautifying vacant areas. One vacant lot greening initiative, which greened 4,436 lots in 4 areas of Philadelphia, PA, greening significantly reduced community residents' self-reported stress levels ( $p<.001$ ) and engaged in more physical exercise ( $p<.001$ ) than residents in control vacant lot areas. Other benefits included reductions in firearm assaults and vandalism<sup>5</sup>.

## Teach Coping and Problem-Solving Skills

### Rationale

Building life skills prepare individuals to successfully tackle every day challenges and adapt to stress and adversity. Life skills encompasses many concepts, but most often include coping and problem-solving skills, conflict resolution, and critical thinking. Life skills are important in shielding individuals from suicidal behaviors<sup>6</sup>. Suicide prevention programs that focus on life and social skills training are drawn from social cognitive theories<sup>7</sup>, surmising that individuals who engage in suicidal behavior is attributed to either direct learning, modeling, and environmental and individual (e.g. hopelessness) characteristics. The literature linking life skills and suicide is robust--- The inability to employ adequate coping strategies to cope with immediate stressors or identify and find solutions for problems have been characterized among suicide attempters<sup>8</sup>. Treatments that include bolstering problem skills<sup>9</sup> and include problem-solving techniques<sup>10,11</sup> appear to reduce suicidal ideation and attempts more effectively. Prevention programs focused on teaching these skills target youth, parents and families and have been used with both universal and at-risk populations. While many do not target suicidal behaviors directly, these programs strive to train youth and parents important life skills to offset the underlying vulnerabilities that contribute to engaging in high risk behaviors early in life.

### Approaches

Current evidence provides support for the following two approaches:

- **Social emotional learning programs** focus on developing and strengthening communication and problem-solving skills, emotion regulation, conflict resolution, help seeking and coping skills. These approaches address a range of risk and protective factors for suicidal behavior. They provide children and youth with skills to resolve problems in relationships, school, and with peers, and help youth to address other negative influences (e.g., substance use) associated with suicide. These approaches are typically delivered to all students in a particular grade or school, although some programs also focus on groups of students considered to be at high-risk for suicide. Opportunities to practice and reinforce skills are an important part of programs that work.
- **Parenting skill and family relationship programs** are designed to strengthen parenting skills, enhance positive parent-child interactions, and improve children's behavioral and emotional skills and abilities. Several parenting and family relationship programs have been shown in rigorous evaluations to improve resilience and reduce risk factors for various behaviors, including ones closely related to suicide, such as depression, internalizing behaviors, and substance abuse.

## Potential Outcomes

- Reduction in suicide attempts and suicide ideation
- Enhanced knowledge of risk and protective factors associated with suicide
- Reduction in suicide risk behaviors (i.e., depression, anxiety, conduct problems, substance abuse)
- Improve and normalize help-seeking behavior
- Enhance social competence and emotional regulation skills
- Enhance problem-solving and conflict management skills

## Evidence

There are several programs with evidence that supports teaching social, emotional and parenting skills to reduce suicidal behaviors and associated risk factors.

- **Social emotional learning programs.** These programs, commonly delivered in schools, overall have demonstrated success in preventing suicide risk. However, the evidence is mixed; while most models demonstrated strong effects, others were mixed. For example, *Signs of Suicide (SOS)* is a high school-based prevention program for students designed to increase knowledge about suicide improve and normalize help-seeking behaviors. After 3 months of participation, *SOS* has documented a 64% reduction in suicide attempts among its participants compared to controls. *SOS* participants with a lifetime history of suicide attempt were also significantly less likely to report planning a suicide in the 3 months following the program compared to lower-risk participants. Moreover, increased knowledge of how access help for themselves or friends for depression and/or suicidal thoughts, and favorable attitudes toward help-seeking were noted among students who participated in *SOS*<sup>12</sup>.

Another example is *The Good Behavior Game (GBG)*, which is a classroom-based program for elementary school children uses a behavior management strategy that promotes good behavior by setting clear expectations for good behavior and consequences for maladaptive behavior. In the evaluation of this program, several outcome behaviors were measured including suicide, given its association with externalizing behavior problems. Results from the first cohort evaluation found that first graders assigned to *GBG* reported half the adjusted odds of suicide ideation and suicide attempts than controls. After 14 years postvention, *GBG* was also found to significantly reduce risk of substance abuse<sup>13</sup>. However, in a replication trial, *GBG* did not produce the same reductions on suicide ideation or attempts as it did in the first cohort<sup>14</sup>. This finding likely arose due to the lack of implementation fidelity and pointed to the need for *GBG* to be delivered with precision, consistency, and teacher support (ref??).

Finally, the *Youth Aware of Mental Health Program (YAM)*, a school-based program rigorously evaluated in 10 European countries, teaches youth about suicide risk and protective factors and problem-solving skills. At 12 months, students participating in *YAM* were significantly less likely to have a suicide attempt and severe suicidal ideation compared to controls; Risk of suicide ideation and attempts fell by 49 to 54% among *YAM* participants<sup>15</sup>.

- **Parenting skill and family relationship programs**

Parenting and family skills training approaches have shown promising impacts in preventing key risk factors associated with suicide. One program, *The Incredible Years* is a universally delivered program for parents of children up to 12 years of age designed to improve responsive and positive parent-teacher-child interactions and relationships, emotion self-regulation and social competence and reduce problem behaviors in children. Several studies have demonstrated the effect of *The Incredible Years* program on reducing internalizing symptoms, such as anxiety and depression, and child conduct problems<sup>16,17,18,19</sup>. The program is also associated with improved problem-solving and conflict management, skills that were maintained at 1-year follow-up<sup>17,18,19</sup>. The program also demonstrated greater benefits as the dosage of the intervention increased<sup>20</sup>. *Strengthening Families 10-14 years* is a program that involves sessions between parents, youth, and family with the goals of: 1) improving parents' skills for disciplining, managing emotions and conflict, and communicating with their children; 2) promoting youths' interpersonal and problem-solving skills; and 3) creating family activities to build cohesion and positive parent-child interactions. The program has successfully shown to decrease externalizing behaviors, alcohol use, and drug use among youth participants and reductions in depression, alcohol use, and drug use among participating families<sup>21</sup>.

## Identify and Support People At-Risk

### Rationale

In order to be successful in decreasing suicidal behavior, attention must be paid to those who are at-risk or vulnerable. These persons experience risk and occurrence of suicidal behavior that is higher than average. This group requires particular focus on proactive case finding and retention and access to services. These vulnerable or disadvantaged populations include (but are not limited to): those living in lower socio-economic status; members of certain ethnic minority groups; those with a mental health problem; those who are institutionalized; those who have been victims of violence; and those who are homeless. Finding effective ways of identifying at-risk or vulnerable groups, customizing services to make them accessible and maintaining care are still key challenges. For example, simply improving services does not guarantee that those services will be used by those most in need of them. Nor will it necessarily increase the number of people who follow treatments that are recommended. People who are disadvantaged face social and economic issues that may adversely affect their ability to respond to the treatments or advice that are offered.

### Approaches

This document outlines three approaches that focus on identifying and supporting those who are at-risk.

- **Gatekeeper training** is typically implemented in schools and within health care settings and is designed to train teachers, coaches, providers and others in the community to identify people who may be at risk of suicide and to respond effectively, including facilitating treatment seeking and support services.
- **Screening combined with care management and overall continuity of care** has been used in primary care and behavioral health care to assure that people who may be at high-risk of suicide don't 'slip through the cracks'. These approaches typically employ screening for depression and/or suicide combined with collaborative treatment planning between patients and their providers and patient follow-up. Programs such as these have demonstrated beneficial effects on depression, suicide ideation, and suicide mortality.
- **Crisis intervention.** These approaches provide support and referral services, typically by connecting a person in crisis (or a friend or family member of someone at-risk) to trained volunteers and/or professional staff via telephone hotline, online chat, or text messaging. Crisis intervention approaches are intended to impact key risk factors for suicide, including feelings of depression, hopelessness, and subsequent mental health care utilization. Like means restriction,

crisis interventions can put space or time between an individual who may be considering suicide and harmful behavior.

### Potential Outcomes

- Reduction in suicide attempts
- Reduction in suicide deaths
- Increased identification of individuals at-risk for suicidal behavior
- Increased at-risk individuals in treatment
- Increased community members trained to identify at-risk individuals
- Increased referrals for health care

### Evidence

- There is evidence that community gatekeeper programs are successful in reducing suicides and suicide attempts but the efforts must be maintained. (Substance Abuse and Mental Health Services Administration, Center for Mental Health Services. Report to Congress: Garret Lee Smith Suicide Prevention Program. US Department of Health and Human Services: Rockville, MD, 2014). There is limited evidence for effectiveness screening programs but standard principles for public health screening make them promising. (Pena JB, Caine ED. Screening as an Approach for Adolescent Suicide Prevention. *Suicide and Life-Threatening Behavior*. 2006; 36(6):614-637. The number of studies evaluating crisis intervention services is limited but a few studies do indicate that those who use the hotline services have decreased suicidal thoughts and behavior.
- **Gatekeeper training.**  
*Mental Health First Aid (MHFA)*, designed for the lay public, consists of three weekly sessions of three hours each. The content covers helping people in mental health crises and/or in the early stages of mental health problems. The crisis situations covered included suicidal thoughts and behavior, acute stress reaction, panic attacks and acute psychotic behavior. The mental health problems discussed included depressive, anxiety and psychotic disorders. The co-morbidity with substance use disorders is also covered. Participants learn the symptoms of these disorders, possible risk factors, where and how to get help and evidence-based effective help. In a randomized controlled trial of 300 participants, the intervention group reported greater confidence in providing help to others, greater likelihood of advising people to seek professional help, improved concordance with health professionals about treatments, and decreased stigmatizing attitudes. An additional finding was an improvement in the mental health of the participants themselves. All results were statistically significant at  $p < .05$ . (Kitchener & Jorm,

2004). Additional research rigorously evaluating MHFA for its impact on the first aid recipients themselves and suicidal behavior is needed (Kitchener & Jorm, 2006).

*Garret Lee Smith (GLS) Suicide Prevention Program*, as of June 2014, 154 GLS grants had been awarded to 49 states and 48 tribes. Gatekeeper training has been a core part of all GLS programs, and grantees have consistently reported spending the largest proportion of their budget on this strategy. A multi-site evaluation assessed the connection between community gatekeeper training (activities such as the number of people trained and the intended mid- and long-term outcomes) and a reduction of suicide attempts and deaths. To address this question, the analysis compared the change in the suicide mortality rates and nonfatal suicidal behavior among the population aged youth and young adults in counties implementing GLS trainings, with the trajectory observed in similar counties that did not implement these trainings. Effect on fatal behavior - When compared with similar counties that did not implement GLS training, counties implementing GLS trainings presented significantly lower youth suicide rates the year following the training implementation (-1.07,  $p=.03$ ). This finding represents a decrease of 1 suicide death per 100,000 10 to 24 year olds or the avoidance of approximately 237 deaths in this age group between 2007 and 2010. Effect on nonfatal behavior - Counties implementing GLS program activities had significantly lower suicide attempt rates among youths 16 to 23 years of age in the year following implementation of the GLS program than did similar counties that did not implement GLS program activities (4.9 fewer attempts per 1000 youths [95% CI, 1.8-8.0 fewer attempts per 1000 youths];  $P = .003$ ). More than 79 000 suicide attempts may have been averted during the period studied following implementation of the GLS program.

Walrath C, Godoy-Garraza L, Reid H, Goldston DB, McKeon R. Impact of the Garrett Lee Smith Youth Suicide Prevention Program on Suicide Mortality. *American Journal of Public Health*: May 2015, Vol. 105, No. 5, pp. 986-993. doi: 10.2105/AJPH.2014.302496.

Godoy Garraza L, Walrath C, Goldston DB, Reid H, McKeon R. Effect of the Garrett Lee Smith Memorial Suicide Prevention Program on Suicide Attempts Among Youths. *JAMA Psychiatry*. 2015; 72:1143-1149. doi:10.1001/jamapsychiatry.2015.1933. I Brief statement introducing the evidence.

- **Screening combined with care management and overall continuity of care.**

*Henry Ford Perfect Depression Care (Pre-cursor to Zero Suicide)* The overall goal of the program was to eliminate suicide. More broadly, the aim of the program was to completely redesign depression care delivery to achieve breakthrough improvement in quality and safety. The redesign focused on six aims: effectiveness, safety, patient centeredness, timeliness, efficiency, and equity among patients. The program developed concrete measures to assess progress on each of these aims. The program began with screening and assessment of each patient for suicide

risk with coordinated continuous follow-up care system wide. On the basis of the combined total of 31 suicides for the 11-year observation period, the rate of suicide among patients was 97 per 100,000 (N=13) for the two baseline years (the average rate for 1999 and 2000). This rate is similar to that reported for a clinical population. For the start-up year (2001), the rate of suicide was 41 per 100,000 (N=3). For the follow-up interval (the average for 2002–2009), the rate was 19 per 100,000 (N=15). Poisson regression analysis showed a statistically significant decrease of 82% in the suicide death rate between the baseline (1999–2000) and intervention (2002–2009) years (rate ratio=.20; 95% confidence interval=.16–.24,  $p \leq .001$ ). Coffey et al., 2013; Coffey, 2006. Additionally, between 1999 and 2010, researchers found that suicide rates declined among HMO members who received mental health specialty services, in association with a target prevention effort, and increased among HMO members who accessed general medical services but not specialty MH services (Coffey et. al., 2015).

- **Crisis intervention.**

*National Suicide Prevention Lifeline (NSPL).* This is a nationwide hotline that operates 24/7 and is accessible by phone or a web-based chat function. Trained counselors are on-hand to listen, offer free and confidential emotional support, and provide referrals for mental health services in the local area. Suicide callers (N=1,085) were assessed during their calls to the hotline and 380 (35.0%) participated in the follow-up assessment. Results indicated that seriously suicidal individuals called the hotline. Significant decreases in suicidality were found during the course of the telephone session, with continuing decreases in hopelessness and psychological pain in the following weeks (Gould et al., 2007).

- *Applied Suicide Intervention Skills Training (ASIST).* This a training program for hotline counselors, emergency workers, clergy, caregivers and others in the community. The ASIST model has three phases of caregiving: connecting, understanding and assisting. The training helps participants identify people who are having thoughts of suicide and to recognize their invitation for help (connecting); to listen to the caller's reasons for dying and living (understanding); and how to conduct a safety assessment, develop a safety plan for the person at risk, and connect the person at risk to community resources (assisting). The ASIST training program has been field tested in a variety of settings. In a national randomized controlled trial, Gould et al (2013) assessed the impact of the ASIST training across the NSPL network of hotlines over the period 2008-2009. Data were derived from 1,507 monitored calls from 1,410 suicidal individuals to 17 Lifeline centers. Callers who spoke with ASIST-trained counselors were significantly more likely to feel less depressed, less suicidal, less overwhelmed, and more hopeful by the end of calls compared to those who spoke to counselors receiving usual care training. ASIST-trained counselors were also better able to keep callers on the phone longer and

establish a connection. ASIST training, however, did not yield more comprehensive suicide risk assessments than usual care training (Gould et al., 2013).

## Intervene to Lessen Harms and Prevent Future Risk

### Rationale

Individuals who have experienced mental health challenges, suicidal ideation, and have had non-fatal suicide attempts or have engaged in non-suicidal self-injury are at increased risk of subsequent suicide-related morbidity and mortality. Risk of suicidality can also increase among those who have lost a friend, family member, co-worker, or other acquaintance to suicide. Exposure to sensationalized or uninformed reporting regarding suicide-related deaths may heighten the risk of suicide among vulnerable individuals and can inadvertently contribute to suicide contagion.

### Approaches

A broad array of approaches to lessen harms and reduce future risk of suicidality among those at increased risk include the provision of mental health care and improved continuity of care, improving linkage to care through active post-discharge planning and follow-up that decreases barriers to ongoing therapeutic support, increasing connectedness to supportive others, addressing bereavement, and framing communications to emphasize resilience, decrease negative affect, and to prevent contagion.

- **Treatment for people at-risk of suicide** typically includes various forms of psychotherapy delivered by licensed providers to help individuals with mental health problems and other risk factors for suicide with problem-solving, impulsivity and emotion regulation.
- **Treatment to prevent re-attempts.** These follow-up contact approaches use diverse modalities (e.g., home visits, mail, telephone, e-mail) to engage recent suicide attempt survivors to prevent reattempts. These approaches typically focus on coping and other emotional regulation skills and may include **case management home visits to increase adherence to and continuity of care**, one-on-one interpersonal therapy and/or group therapy. Approaches that engage and connect attempters to peers and providers are especially important because many attempters do not present to aftercare; 12%-25% reattempt within a year, and 3%-9% of attempt survivors die by suicide within 1 to 5 years of their initial attempt (Inagaki, et al., 2015).
- **Postvention** approaches are implemented after a suicide has taken place and may include debriefing of survivors (those who have lost a friend, peer, family member, co-worker to suicide), counseling, and/or bereavement support groups. The programs have not typically tested their impact on suicide or suicidal behavior but may reduce risk of guilt, feelings of depression, and complicated grief (Szumilas et al., 2011). Additionally, research suggests that active postvention approaches in which outreach to suicide survivors occurs at the scene of a suicide is associated with intake into treatment sooner, greater attendance at support group meetings, and attendance at more meetings compared to passive postvention (no outreach) (Cerel & Campbell, 2008).

- **Safe messaging following a suicide.** The manner in which information on a recent suicide is communicated to the public (e.g. school assemblies, mass media, social media) can heighten the risk of suicide among vulnerable individuals and can inadvertently contribute to suicide contagion.

## Potential Outcomes

- Reduction in mental health-related sequelae
- Increase connectedness
- Improved coping skills
- Improved messaging following suicide
- Reduction in re-attempts

## Evidence

The evidence addressing strategies to lesson harm and prevent future risk of suicide includes the evaluation of effects of specific approaches on risk and protective factors as well as suicide-related mortality. However, because the evaluation of suicide-related mortality is a statistically rare event, evaluation of mortality outcomes requires large sample sizes and extended follow-up. Therefore, much of the evidence in this area primarily focuses on risk and protective factors.

- **Treatment for people at-risk of suicide.**

Psychotherapy has been demonstrated to help diverse individuals in different settings to reduce risks related to mental health problems such as depression and anxiety, and to reduce suicidal ideation and attempts. Evaluation evidence for selected psychotherapeutic approaches to prevent future suicide risk follow below.

**Improving Mood – Promoting Access to Collaborative Treatment (IMPACT)** aims to prevent suicide among older primary care patients by reducing suicide ideation and depression in primary care settings. IMPACT facilitates the development of a therapeutic alliance, a personalized treatment plan that includes patient preferences, as well as proactive follow-up (biweekly during an acute phase and monthly during continuation phase) by a depression care manager. IMPACT has been shown to significantly improve quality of life, and to reduce functional impairment, depression (Hunkeler et al., 2006; Unützer et al., 2002) and suicidal ideation over 24-months of follow-up (Unützer et al., 2006) relative to patients who received care as usual.

**Collaborative Assessment and Management of Suicidality (CAMS)** is a therapeutic framework for suicide-specific assessment and treatment of patient's suicide risk. It is a flexible approach that can be used across treatment settings and clinician theoretical orientations. The clinician and patient work together in an interactive assessment process. The patient is highly engaged in the development of their own treatment plan. Every session of CAMS is collaborative and involves the patient's input about what is and is not working. Ultimately, this process is designed to enhance the therapeutic alliance and increase treatment motivation in the suicidal patient. CAMS has been tested and supported in 6 correlational studies (Jobes, 2012), in a variety of inpatient and outpatient settings and in one RCT with several additional RCTs under way. CAMS has been associated with significant improvements in suicidal ideation, overall symptom distress, and feelings of hopelessness at 12 month follow-up among a community-based sample of suicidal outpatients. (Comtois et al., 2011).

**Dialectical Behavioral Therapy** is a multicomponent therapy for individuals at high risk for suicide who may struggle with impulsivity and emotional regulation. The components of DBT include individual therapy, group skills training, between-session telephone coaching and a therapist consultation team. In a randomized controlled trial of women with recent suicidal or self-injurious behavior, those receiving DBT were half as likely to make a suicide attempt at two-year follow-up than women receiving community treatment (23% vs 46%), required less hospitalization for suicide ideation, and had lower medical risk across all suicide attempts and self-injurious acts combined (Linehan et al., 2006).

**Attachment-Based Family Therapy (ABFT)** is a program for adolescents ages 12-18 that is designed to treat clinically diagnosed major depressive disorder, eliminate suicidal ideation, and reduce dispositional anxiety. A randomized controlled trial of ABFT (Diamond et al., 2010) found that suicidal adolescents assigned to ABFT experienced significantly greater improvement regarding suicidal ideation over 24 weeks of follow-up than did adolescents assigned to enhanced usual care (-4.37 vs. -2.34;  $p = .001$ ;  $d=0.97$ ). A higher percentage of ABFT participants reported no suicidal ideation in the past week at 12 weeks than did adolescents receiving enhanced usual care (69.2% vs. 34.6%;  $p = .01$ ;  $OR= 4.25$ ) and at 24 weeks (82.1% vs. 46.2%;  $p = .006$ ;  $OR=5.37$ ).

- **Treatment to prevent re-attempts.**

Active contact and follow-up approaches intended to prevent reattempts among patients that have been hospitalized and subsequently discharged for suicide attempts have been found in a meta-analysis conducted by Inagaki et al., (2015) to reduce reattempts by approximately 17% for up to 12 months post-discharge, however, the long-term effects of these approaches on reattempts has not yet been demonstrated. Also, because the number of trials and associated sample sizes included in this meta-analysis were small, it was not possible to determine the effect

of active contact and follow-up approaches on death by suicide. In a randomized controlled trial of postcrisis suicide prevention long-term follow-up contact approach, Motto et al., (2001) found that patients who refused ongoing care but who were randomized to be contacted by letter four times per year had a lower rate of suicide over two years of follow-up than did patients in the control group who received no further contact. Other studies have also shown post-crisis letters and coping cards to be protective against suicide ideation and attempts (Hassanian-Moghaddam et al., 2011; Wang et al., 2016).

- **Postvention** approaches such as *StandBy Response Service* provide suicide bereavement support services to clients via face-to-face outreach and telephone support delivered by a professional crisis response team. A site coordinator develops a customized case management plan, referring clients to other existing community services matched to their needs. In a study by Visser et al. (2014), *StandBy* clients were significantly less likely to be at high risk for suicidality than a suicide bereaved comparison group who had not had contact with the *StandBy* program (48% and 64% respectively,  $p = 0.005$ ).
- **Safe messaging following a suicide.** *Media* guidelines for reporting on suicides can help assure that stories on suicide are communicated in a safe and effective way. Reports that are both inclusive of suicide prevention messages, stories of hope and resilience, risk and protective factors, and links to helping resources (e.g., hotline) and that avoid sensationalizing events or reducing suicide to one cause can help reduce the likelihood of suicide contagion. The most compelling evidence supporting the effect of media guidelines on reduction in suicides comes from Austria. After a sharp increase in suicides on the Viennese subway, media guidelines were introduced and an interrupted time series design was used to evaluate the national impact of the guidelines on subsequent suicides. Changes in the quality and quantity of media reporting resulted in a reduction of 81 suicides annually (95% confidence interval: -149 to -13;  $t = -2.32$ ,  $df = 54$ ,  $p < 0.024$ ) in the Viennese subway system (Niederkrötenhaller, T., & Sonneck, G., 2007)

## Sector Involvement

Public health can play an important and unique role in addressing suicide. Public health agencies, which typically place prevention at the forefront of efforts and work to create broad population-level impact, can bring critical leadership and resources to bear on this problem. For example, these agencies can serve as a convener, bringing together partners and stakeholders to plan, prioritize, and coordinate suicide prevention efforts. Public health agencies are also well positioned to collect and disseminate data, implement preventive measures, evaluate programs, and track progress. Although public health can play a leadership role in preventing suicide, the strategies and approaches outlined in this technical package cannot be accomplished by the public health sector alone.

Other sectors vital to implementing this package include, but are not limited to, education, government (local, state, and federal), social services, health services, business/labor, justice, housing, media, and organizations that comprise the civil society sector such as faith-based organizations, youth-serving organizations, foundations, and other non-governmental organizations. Collectively, these sectors can

make a difference in preventing suicide by impacting the various contexts and underlying risks that contribute to suicide.

The strategies and approaches described in this technical package are summarized in Appendix A along with the relevant sectors that are well positioned to lead implementation efforts.

[I can write the text specific to the strategies and approaches. I've done this for the other TPs and am happy to do the same here. This is the section where we distinguish the strategies where public health is best positioned to lead from those where leadership is necessary from other sectors and how public health can assist, etc.]

Regardless of strategy, action by many sectors will be necessary for the successful implementation of this package. In this regard, all sectors can play an important and influential role in.....

## Monitoring and Evaluation

Monitoring and evaluation are necessary components of the public health approach to prevention. It is important to have timely and reliable data to monitor the extent of the problem and to evaluate the impact of prevention efforts. Data are necessary for program implementation; planning, implementation, and assessment all rely on accurate measurement of the problem.

Surveillance data helps researchers and practitioners track changes in the burden of suicide. Surveillance systems exist at the federal, state, and local levels. It is important to assess the availability of surveillance data and data systems across these levels to identify and address gaps in the systems. CDC's National Vital Statistics System and the National Violent Death Reporting System (NVDRS) are examples of surveillance systems that provide data on deaths from suicide. NVDRS, for example, is a state-based surveillance system that combines data from death certificates, law enforcement reports, and coroner or medical examiner reports to provide detailed information on the circumstances of violent deaths, including suicide, which can assist communities in guiding prevention approaches (Blair et al., 2016). The National Electronic Injury Surveillance System-All Injury Program (NEISS-AIP) provides nationally representative data about all types and causes of nonfatal injuries treated in U.S. hospital emergency departments, and can be used to assess national rates of, and trends in, self-harm injuries by cause (e.g., falls, poisoning, etc.), age, race/ethnicity, sex, disposition (where the injured person goes when released from the Emergency Department (<http://www.cdc.gov/injury/wisqars/nonfatal.html>)).

In addition to information on deaths and nonfatal injuries, there are also surveillance systems that provide national, state, and some local estimates of suicidal behavior. The Youth Risk Behavior Surveillance System (YRBSS) collects information from a nationally representative sample of 9-12 grade students and is a key resource in monitoring health-risk behaviors among youth, including whether youth have seriously considered attempting suicide, attempted suicide, made a plan, or required treatment by a doctor or nurse for a suicide attempt that resulted in an injury, poisoning, or overdose (Brener et al., 2013). The YRBSS data are obtained from a national school-based survey conducted by CDC as well as school-based state, territorial, tribal, and large urban school district survey conducted by education and health agencies. The National Survey on Drug Use and Health (NSDUH) is an annual nationwide survey of individuals aged 12 years and older that provides national and state-level estimates of drug use and mental health-related issues, including suicide ideation and suicide attempts (<https://nsduhweb.rti.org/respweb/homepage.cfm>).

It is also important at all levels (local, state, and federal) to address gaps in responses, track progress of prevention efforts and evaluate the impact of those efforts, including the impact of this technical package. Evaluation data, produced through program implementation and monitoring, is essential to provide information on what does and does not work to reduce rates of suicide and its associated risk and protective factors. Theories of change and logic models that identify short, intermediate, and long-term outcomes are an important part of program evaluation.

The evidence-base for suicide prevention has advanced greatly over the last few decades. However, additional research is needed to..... Lastly, it will be important for researchers to test the effectiveness of combinations of the strategies and approaches included in this package. Most existing evaluations focus on approaches implemented in isolation. However, there is potential to understand the synergistic effects within a comprehensive prevention approach. Additional research is needed to understand the extent to which combinations of strategies and approaches result in greater reductions in suicide than individual programs, practices, or policies.

## Conclusion

## Appendix A: Summary of Strategies and Approaches to Prevent Suicide

Strategy	Approach/Program, Practice or Policy	Best Available Evidence			Lead Sectors <sup>1</sup>
		Suicide	Suicide Attempts or Ideation	Other Risk/Protective Factors for Suicide	
Strengthen economic supports	<b>Strengthen financial security</b>				
	<i>Unemployment benefit programs</i>				
	<b>Housing stabilization policies</b>				
	<i>The National Neighborhood Stabilization Program</i>				
Strengthen access to mental health care	<b>Coverage of mental health conditions in health insurance policies</b>				
	<i>Mental Health Parity Laws</i>				
Establish protective environments	<b>Means restriction</b>				
	<i>Intervening at hot spots</i>	X			
	<i>Safe storage practices</i>		X (attempts)	X (Safe storage of firearms and medication)	
	<b>Organizational policies and culture</b>				
	<i>Together for Life</i>	X			
	<i>US Air Force Suicide Prevention Program</i>	X		X (family violence)	

**Comment [A]:** I'll help you complete the lead sector column. For the other columns, you just need to insert a check-mark based on the evidence you describe in the narrative for a particular program or policy. For example, if the evidence shows impact on suicide, then put a check-mark in that column. If the study also found effects on risk or protective factors, then put a check-mark in that column as well.

		Best Available Evidence			
	Community-based policies to reduce excessive alcohol use				
	Alcohol outlet density				
Promote connectedness to protect against suicide	Peer norm approaches				
	Sources of Strength			√	
	Community-engagement activities				
	Greening vacant urban spaces			√	
Teach coping and problem-solving skills	Social emotional learning				
	Youth Aware of Mental Health Program		√		
	Signs of Suicide		√	√	
	Good Behavior Game		√	√	
	Parenting skill and family relationship approaches				
	The Incredible Years			√	
	Strengthening Families 10-14			√	
	Gatekeeper training				
	Mental Health First Aid				

		Best Available Evidence			
Identify and support people at-risk	Screening combined with care management				
	Henry Ford Perfect Depression Care (Precursor to Zero Suicide)				
	Crisis Intervention				
	National Suicide Prevention Lifeline				
	Applied Suicide Intervention Skills Training				
Intervene to lessen harms and prevent future risk	Treatment for people at risk of suicide				
	Improving Mood – Promoting Access to Collaborative Treatment (IMPACT)				
	Collaborative Assessment and Management of Suicidality (CAMS)				
	Dialectical Behavioral Therapy				
	Attachment-Based Family Therapy				
	Treatment to prevent re-attempts				
	ED Brief Intervention with Follow-up Visits				
	Active follow-up contact approaches				
	CBT for Suicide Prevention				

	Best Available Evidence				
	<b>Postvention</b>				
	<i>StandBy Response Service</i>				
	<b>Safe messaging following a suicide</b>				
	<i>Media Guidelines</i>				-

<sup>1</sup>This column refers to the lead sectors well positioned to bring leadership and resources to implementation efforts. For each strategy, there are many other sectors such as non-governmental organizations that are instrumental to prevention planning and implementing the specific programmatic activities.

## Overview

This technical package represents a select group of strategies based on the best available evidence to help communities and states sharpen their focus on prevention activities with the greatest potential to prevent suicide. These strategies include strengthening economic supports; strengthening access to mental health care; creating protective environments; promoting connectedness; teaching coping and problem-solving skills; identifying and supporting people at-risk; and intervening to lessen harms and prevent future risk. The strategies represented in this package include those with a focus on preventing suicide from happening in the first place as well as approaches to lessen the immediate and long-term harms of suicidal behavior for individuals, families, communities, and society. The strategies in the technical package support the goals and objectives of the National Strategy for Suicide Prevention and the National Action Alliance for Suicide Prevention's priority to strengthen community-based prevention. Commitment, cooperation, and leadership from numerous sectors, including public health, education, justice, health care, social services, business, labor, and government can bring about the successful implementation of this package.

### What is a Technical Package?

A technical package is a compilation of a core set of strategies to achieve and sustain substantial reductions in a specific risk factor or outcome (Frieden, 2014). Technical packages help communities and states prioritize prevention activities based on the best available evidence. This technical package has three components. The first component is the **strategy** or the preventive direction or actions to achieve the goal of preventing suicide. The second component is the **approach**. The approach includes the specific ways to advance the strategy. This can be accomplished through *programs, policies, and practices*. The approaches included come primarily from studies based in the United States. The **evidence** for each of the approaches in preventing suicide or its associated risk factors is included as the third component. This package is intended as a resource to guide and inform prevention decision-making in communities and states.

### Preventing Suicide is a Priority

Suicide, as defined by the Centers for Disease Control and Prevention (CDC), is part of a broader class of behavior called *self-directed violence*. Self-directed violence refers to behavior directed at oneself that deliberately results in injury or the *potential* for injury (A.E. Crosby, Ortega, & Melanson, 2011). Self-directed violence may be *suicidal* or *non-suicidal* in nature. For the purposes of this document, we refer only to behavior where suicide is intended:

- **Suicide** is a death caused by self-directed injurious behavior with any intent to die as a result of the behavior.

- **Suicide attempt** is defined as a *non-fatal* self-directed and potentially injurious behavior with any intent to die as a result of the behavior. A suicide attempt may or may not result in injury.

**Suicide is highly prevalent.** Suicide presents a major challenge to public health in the United States and worldwide. It contributes to premature death, morbidity, lost productivity, and health care costs (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014). In 2014 (the most recent year of available death data), suicide was responsible for 42,773 deaths in the U.S., which is approximately one suicide every 12 minutes (Centers for Disease Control and Prevention, 2016d). In 2014, suicide ranked as the 10th leading cause of death and has been among the top 12 leading causes of death since 1975 in the U.S (Centers for Disease Control and Prevention, 2016d). Overall suicide rates have increased 24% from 1999 to 2014 (Curtin, Warner, & Hedegaard, 2016). Suicide is a problem throughout the life span; it is the second leading cause of death among those aged 10–34 years; it is the fourth leading cause among persons in their 40s and seventh among persons in their 50s. Suicide rates vary by race/ethnicity with the highest rates, across the lifespan, occurring among non-Hispanic American Indian/Alaska Native (AI/AN) (rate: 17.8/100,000). Among AI/AN, young people are disproportionately at increased risk of suicide with young males aged 25-29 experiencing the highest rates (rate: 56.9/100,000). Moreover, suicide rates among non-Hispanic AI/AN have increased by 48.7% since 1999 (Centers for Disease Control and Prevention, 2016d).

Suicides reflect only a portion of the problem (A.E. Crosby, Han, Ortega, Parks, & Gfroerer, 2011). Substantially more people are hospitalized as a result of nonfatal suicidal behavior (i.e. suicide attempts) than are fatally injured, and an even greater number are either treated in ambulatory settings (e.g., emergency departments) or not treated at all (A.E. Crosby, Han, et al., 2011). For example, during 2014, among adults aged 18 years and older, for every one suicide there were 9 adults treated in hospital emergency departments for self-harm injuries, 27 who reported making a suicide attempt, and over 227 who reported seriously considering suicide (i.e. ideation) (Ferdon et al., In press).

**Suicide is associated with several risk and protective factors.** Suicide, like other human behaviors, has no single determining cause. Instead, suicide occurs in response to multiple biological, psychological, interpersonal, environmental and societal influences that interact with one another, often over time. The social-ecological model-- encompassing multiple levels of focus from the individual, relationship, community, and societal-- is a useful framework for viewing and understanding suicide risk factors identified in the literature (Dahlberg & Krug, 2002). Risk and protective factors for suicide exist at each level. For example, risk factors include:

- **Individual level:** History of depression and other mental illnesses, hopelessness, substance abuse, certain health conditions, previous suicide attempt, violence victimization and perpetration, and genetic and biological determinants
- **Relationship level:** High conflict or violent relationships, sense of isolation and lack of social support, family/loved one's history of suicide, financial and work stress

- **Community level:** Inadequate community connectedness, barriers to health care (e.g., lack of access to providers and medications)
- **Societal level:** Availability of lethal means of suicide, unsafe media portrayals of suicide, stigma associated with help-seeking and mental illness (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014).

It is important to recognize that the vast majority of individuals who are depressed or who have other risk factors noted, do *not* die by suicide. Furthermore, the relevance of each risk factor can vary by age, race, gender, sexual orientation, residential geography, and socio-cultural and economic status (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014).

Protective factors, or those influences that guard *against* the risk for suicide, can also be found across the different levels of the social-ecological model. Protective factors identified in the literature include: effective coping and problem solving skills, moral objections to suicide, strong and supportive relationships with partners, friends, and family; connectedness to school, community and other social institutions; availability of quality and ongoing physical and mental health care, and reduced access to lethal means (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014). These protective factors can either counter a specific risk factor or guard against a number of risks associated with suicide.

**Suicide is connected to other forms of violence.** Suicide and other forms of violence often share some of the same root causes (Butchart, Phinney, Check, & Villaveces, 2004; Klevens, Simon, & Chen, 2012). For example, in neighborhoods where there is low social cohesion, or where residents don't support and trust each other, people are at higher risk for suicide (Desai, Dausey, & Rosenheck, 2005) as well as perpetration of child maltreatment (Coulton, Crampton, Irwin, Spilsbury, & Korbin, 2007; Freisthler, Merritt, & LaScala, 2006), teen dating violence (Capaldi, Knoble, Shortt, & Kim, 2012), intimate partner violence (Pinchevsky & Wright, 2012), and youth violence (Sampson, Morenoff, & Gannon-Rowley, 2002). Additionally, a lack of economic opportunities and unemployment are associated with suicide (Luo, Florence, Quispe-Agnoli, Ouyang, & Crosby, 2011; Reeves et al., 2012), as well as perpetration of child maltreatment (D. Runyan, Wattam, Ikeda, Hassan, & Ramiro, 2002), intimate partner violence (Heise & Garcia-Moreno, 2002; Pinchevsky & Wright, 2012), sexual violence (Centers for Disease Control and Prevention, 2016c) and youth violence (Wilson, 2011). Other shared risk factors for suicide and violence occur at the individual level and include substance abuse, mental health problems, witnessing violence, and a lack of problem-solving skills (Centers for Disease Control and Prevention, 2016a, 2016c, 2016e; U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012).

Just as risk factors may be shared across suicide and violence, so too may protective factors overlap. For example, ~~connectedness increases individual's and communities' resilience to suicide and other forms~~

~~(of violence, including connectedness to one's community)~~ (Basile, Hamburger, Swahn, & Choi, 2013; Borowsky, Hogan, & Ireland, 1997; Centers for Disease Control and Prevention, 2016b; Coulton et al., 2007; Kleiman, Riskind, Schaefer, & Weingarden, 2012; Pinchevsky & Wright, 2012; Widome, Sieving, Harpin, & Hearst, 2008), school (Basile, Espelage, Rivers, McMahon, & Simon, 2009; Capaldi et al., 2012; Carter, McGee, Taylor, & Williams, 2007; DeGue et al., 2013; Hong, Kral, Espelage, & Allen-Meares, 2012; Losel & Farrington, 2012), family (Capaldi et al., 2012; Centers for Disease Control and Prevention, 2016a; Elgar, Craig, Boyce, Morgan, & Vella-Zarb, 2009; Maimon, Browning, & Brooks-Gunn, 2010; Resnick, Ireland, & Borowsky, 2004), caring adults (Capaldi et al., 2012; Losel & Farrington, 2012; Maimon et al., 2010), and pro-social peers (Capaldi et al., 2012; Losel & Farrington, 2012) enhances resilience to suicide and other forms of violence.

**The health and economic consequences of suicide are substantial.** Suicide and suicide attempts have far-reaching consequences for individuals, families, and communities (Dunne, McIntosh, & Dunne-Maxim, 1987; Mishara, 1995; National Action Alliance for Suicide Prevention: Suicide Attempt Survivors Task Force, 2014; National Action Alliance for Suicide Prevention: Survivors of Suicide Loss Task Force, 2015). ~~By one conservative estimate, for every death by suicide six people are directly impacted (i.e. survivors). Based on this figure it is estimated that there are over 13 million survivors in the U.S. and unfortunately, survivorship itself is a risk factor for suicide (Crosby & Sacks, 2002).~~ Research indicates that the health consequences of suicide, are also much more extensive than injury and death. In an early study, Crosby and Sacks (2002) estimated that 7% of the U.S. adult population, or 13.2 million adults, knew someone in the prior 12 months who had died by suicide. They also estimated that for each suicide, 425 adults were exposed, or knew about the death. In a more recent study, in one state, Cerel et. al (2016) found that 48% of the weighted survey population knew at least one person who died by suicide in their lifetimes. Research indicates that the impact of knowing someone who died by suicide and/or having lived experience (i.e. having attempted suicide oneself) is much more extensive than injury and death. People with lived experience may suffer long-term health and mental health consequences ranging from anger, guilt, and physical impairment, depending on the means and severity of the attempt (Chapman & Dixon-Gordon, 2007). Similarly, survivors of a loved one's suicide may experience ongoing pain and suffering including complicated grief (Mitchell, Kim, Prigerson, & Mortimer-Stephens, 2004), stigma, depression, anxiety, post-traumatic stress disorder, and increased risk of suicidal ideation and suicide (Julie Cerel, McIntosh, Neimeyer, Maple, & Marshall, 2014; Sudak, Maxim, & Carpenter, 2008). Less discussed but no less important, are the financial and occupational effects for those left behind (Florence, Simon, Haegerich, Luo, & Zhou, 2015).

The economic toll of suicide is immense as well. According to conservative estimates, in 2013, suicide cost \$50.8 billion in estimated lifetime medical and work-loss costs (Florence et al., 2015). By another estimate, ~~the total lifetime costs associated with nonfatal injuries and deaths caused by self-directed violence in 2013 were approximately \$93.5 billion after adjusting for under-reporting of suicide (Shepard, Gurewich, Lwin, Reed, & Silverman, 2016).~~ The overwhelming burden of these costs results

**Comment [A]:** From TS: I found this wording somewhat awkward.

**Comment [A]:** From LLD: The Crosby & Sacks reference is missing from the reference list. I looked it up online and noticed that the 13 million estimate is based on knowing a suicide decedent in the past year. Knowing someone who died by suicide seems potentially broader to me than being directly impacted.

**Comment [A]:** From TS: Has anyone updated this? It would be good to check.

**Comment [A]:** From LLD: they may also be impacted in other ways (e.g., loss of family income, etc.)

**Comment [A]:** From TS: It seems like it would be appropriate to acknowledge the CDC estimate too. Consider using that as a minimum and then say that others have estimated that the costs could be considerably higher after adjusting for under-reporting of suicide.

from lost productivity over the life course, with the average cost per suicide being over \$1.3 million (Shepard et al., 2016).

**Suicide can be prevented.** Despite the myths surrounding suicide, like most public health problems, suicide is preventable (U.S. Public Health Service, 1999). And while progress will continue to be made into the future, evidence for numerous programs, practices, and policies currently exists, and many programs are ready to be implemented now. Just as suicide is not caused by a single factor, research suggests that suicide will not be prevented by any single intervention taking place in any single setting (Silverman & Maris, 1995; U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012). Rather, suicide prevention is best achieved by a focus across the individual, relationship, family, community, and societal-levels and across all sectors, private and public (e.g., business, public health, physical and behavioral healthcare, justice, education, labor) (National Action Alliance for Suicide Prevention, 2014; World Health Organization, 2014).

### Assessing the Evidence

This technical package includes programs, practices, and policies with evidence of impact on suicide or risk or protective factors for suicide. To be considered for inclusion in the technical package, the program, practice, or policy selected had to meet at least one of these criteria: a) meta-analyses or systematic reviews showing impact on suicide; b) evidence from at least one rigorous (e.g., randomized controlled trial [RCT] or quasi-experimental design) evaluation study that found significant preventive effects on suicide; c) meta-analyses or systematic reviews showing impact on risk or protective factors for suicide, or d) evidence from at least one rigorous (e.g., RCT or quasi-experimental design) evaluation study that found significant impacts on risk or protective factors for suicide. Finally, consideration was also given to the likelihood of achieving beneficial effects on multiple forms of violence; no evidence of harmful effects on specific outcomes or with particular subgroups; and feasibility of implementation in a U.S. context if the program, policy, or practice has been evaluated in another country.

Within this technical package, some approaches do not yet have research evidence demonstrating impact on rates of suicide but instead are supported by evidence indicating impacts on risk or protective factors for suicide (e.g., help-seeking, stigma reduction, depression, connectedness). In terms of the strength of the evidence, programs that have demonstrated effects on suicidal behavior (e.g., reductions in deaths, attempts) provide a higher-level of evidence, but the evidence base is not that strong in all areas. For instance, there has been less evaluation of community engagement and family programs on suicidal behavior. Thus, approaches in this package that have effects on risk or protective factors reflect the (developing mental) nature of the evidence base and the use of the best available evidence at a given time.

It is also important to note that there is often significant heterogeneity among the programs, policies, or practices that fall within one approach or strategy area in terms of the nature and quality of the available

**Comment [A]:** From TS: “developmental nature” doesn’t seem correct. Do you mean the “current status”

evidence. Not all programs, policies, or practices that utilize the same approach (e.g., gatekeeper training) are equally effective, and even those that are effective may not work across all populations. Tailoring programs and more evaluation may be necessary to address different population groups. The examples provided are not intended to be a comprehensive list of evidence-based programs, policies, or practices for each approach, but rather illustrate models that have been shown to impact suicide or have beneficial effects on risk or protective factors for suicide. In practice, the effectiveness of the programs, policies and practices identified in this package will be strongly dependent on the quality of their implementation and the communities in which they are implemented. Implementation guidance to assist practitioners, organizations and communities will be developed separately.

### Context and Cross-Cutting Themes

The strategies and approaches that have been included in this technical package represent different levels of the social ecology, with efforts intended to impact the community and societal levels, as well individual and relationship levels. The strategies and approaches are intended to work in combination and reinforce each other to prevent suicide (see box below). The strategies are arranged in order such that those strategies hypothesized to have the greatest potential for broad public health impact on suicide are included first, followed by those that might impact more select populations (e.g., persons who have already made a suicide attempt).

Preventing Suicide	
Strategy	Approach
Strengthen economic supports	<ul style="list-style-type: none"> <li>Strengthen household financial security</li> <li>Housing stabilization policies</li> </ul>
Strengthen access to mental health care	<ul style="list-style-type: none"> <li>Coverage of mental health conditions in health insurance policies</li> </ul>
Create protective environments	<ul style="list-style-type: none"> <li>Reducing access to lethal means among persons at-risk of suicide</li> <li>Organizational policies and culture</li> <li>Community-based policies to reduce excessive alcohol use</li> </ul>
Promote connectedness	<ul style="list-style-type: none"> <li>Peer norm approaches</li> <li>Community engagement activities</li> </ul>
Teach coping and problem-solving skills	<ul style="list-style-type: none"> <li>Social-emotional learning</li> <li>Parenting skill and family relationship approaches</li> </ul>
Identify and support people at risk	<ul style="list-style-type: none"> <li>Gatekeeper training</li> <li>Screening combined with care management</li> </ul>

	<ul style="list-style-type: none"> <li>• Crisis intervention</li> </ul>
Intervene to lessen harms and prevent future risk	<ul style="list-style-type: none"> <li>• Treatment for people at-risk of suicide</li> <li>• Treatment to prevent re-attempts</li> <li>• Postvention</li> <li>• Safe messaging following a suicide</li> </ul>

The example programs, policies, and practices have been implemented within particular contexts. The social and cultural context of communities is critically important to take into account when selecting strategies and approaches. Practitioners in the field may be in the best position to assess the needs and strengths of their communities and work with community members to make decisions about the combination of approaches included here that are best suited to their context.

Suicide ideation, attempts, morbidity and mortality vary by gender, race/ethnicity, age, occupation, and other important population characteristics. Barriers to disclosure, help seeking, timely access to quality care, and ongoing support may also vary by population and community characteristics. Ideally, the availability of multiple approaches tailored to the economic, cultural, and environmental context of individuals and communities are desirable as they may increase the likelihood of removing barriers to supportive and effective care and provide opportunities to develop individual and community resilience. These culturally appropriate approaches can then be included in comprehensive strategies to maximize the public health impact on reducing suicide-related morbidity and mortality among individuals and within communities.

This package includes strategies where public health agencies are well positioned to bring leadership and resources to implementation efforts. It also includes strategies where public health can serve as an important collaborator (e.g., strategies addressing community and societal level risks), but where leadership and commitment from other sectors such as business, labor or health care is critical to implement a particular policy or program (e.g., workplace policies; screening combined with care management). The role of various sectors in the implementation of a strategy or approach in preventing suicide is described further in the section on *Sector Involvement*.

In the sections that follow, the strategies and approaches with the best available evidence for preventing suicide are described.

## Strengthen Economic Supports

### Rationale

Studies from the U.S. examining historical trends indicate that suicide rates increase during economic recessions marked by high unemployment rates, job losses, and economic instability and decrease during economic expansions and periods marked by low unemployment rates, particularly for working-age individuals 25 to 64 years old (Luo et al., 2011; Fowler et al., 2015). Economic and financial strain, such as job loss, long periods of unemployment, reduced income, difficulty covering medical, food, and housing expenses, and even the anticipation of such financial stress, can directly ~~or indirectly~~ increase an individual's risk for suicide or indirectly increase risk by exacerbating related physical and mental health problems; buffering these risks can therefore, potentially protect against suicide (Stack & Wasserman, 2007). For example, strengthening economic support systems can help people stay in their homes or obtain affordable housing while also paying for necessities such as food and medical care, job training, child care, among other expenses required for daily living. In providing this support, stress and anxiety and the potential for a crisis situation may be reduced, thereby preventing suicide.

### Approaches

Economic supports for individuals and families can be strengthened by targeting household financial security and ensuring stability in housing during periods of economic stress.

- **Strengthening household financial security** can potentially buffer the risk of suicide by providing individuals with the financial means to lessen the stress and hardship associated with a job loss or other unanticipated financial problems. The provision of unemployment benefits and other forms of temporary assistance, livable wages, medical benefits, and retirement and disability insurance to help cover the cost of necessities or to offset costs in the event of disability, are examples of ways to strengthen household financial security.
- **Housing stabilization policies** aim to keep people in their homes and provide housing options for those in need during times of financial insecurity. This may occur through programs that provide affordable housing such as through government subsidies or through other options available to potential homebuyers such as loan modification programs, move-out planning, or financial counseling services that help minimize the risk or impact of foreclosures and eviction.

### Potential Outcomes

- ~~Reduced~~ Reductions in suicide rates
- ~~Lower~~ Reductions in foreclosure rates
- Reductions in ~~Lower~~ eviction rates
- ~~Reduced~~ Reductions in emotional distress

**Comment [A]:** From TS: I was thinking that it might be good to work in a point about how these risks can be directly or indirectly associated with suicide risk because these stressors can exacerbate relationship as well physical and mental health problems.

**KH:** Agreed. Added some language.

**Comment [A]:** From JH: Consistent tense – reduced vs. reduce

**Comment [A]:** From LLD: the other packages use “Reductions in...”; you may want to consider using similar language for your potential outcomes.

**KH:** Made consistent throughout.

## Evidence

There is evidence suggesting that strengthening household financial security and stabilizing housing can reduce suicide risk.

- **Strengthen household financial security.** An examination of variations in U.S. *unemployment benefit programs* across states demonstrated that the impact of unemployment on suicide was offset in those states that provided greater than average unemployment benefits (Cylus, Glymour, & Avendano, 2014). Another U.S. study examining the link between unemployment and suicide risk using monthly suicide data, length of unemployment, and job losses found that the duration of unemployment, as opposed to just the loss of job, predicted suicide risk (Classen & Dunn, 2012). Together, these results suggest that not only should state unemployment benefit programs be generous in their financial allocations, but also in their duration.

Other measures to strengthen household financial security (e.g., transfer payments related to retirement and disability insurance, unemployment insurance compensation, medical benefits, and other forms of family assistance) have also shown an impact on suicide. A study by Flavin and Radcliff (2009) examined the impact of states' per capita spending on transfer payments, medical benefits, and family assistance (Temporary Assistance to Needy Families – TANF) and total state spending on suicide rates between 1990–2000, controlling for a number of suicide risk factors (e.g., residential mobility, divorce rate, unemployment rate) at the state level. As per capita spending on total transfer payments, medical benefits, and family assistance increased there was an associated decrease in state suicide rates. Moreover, it wasn't spending in general that was associated with the reduction but spending on these types of assistance. In terms of lives saved, Flavin & Radcliff calculated the cost of reducing a state's suicide rate by a full point for the years studied. At the national level, they estimated that 3,000 fewer suicides would occur per year nationwide if every state increased their per capita spending on these types of assistance by \$45 per year (Flavin & Radcliff, 2009). Although this was a correlational study, the results demonstrate the potential benefits of policies that reach particularly vulnerable individuals during periods of great need and increased risk for suicide. More evaluation studies are needed to further understand the outcomes impacted by programs such as these.

- **Housing stabilization policies.** The *National Neighborhood Stabilization Program* was designed to help neighborhoods suffering from high rates of foreclosure and abandonment by slowing the deterioration of the neighborhoods and providing affordable housing options for low, moderate, and middle-income homebuyers. This program also offers financial assistance to eligible individuals for the purchase of a new home. Although this program has not been rigorously evaluated for its impact on suicide outcomes, it addresses foreclosure and eviction, which are

**Comment [A]:** From TS: Consider including a point about this being a correlational study and more evaluation work is needed but it suggests the potential benefits of policies that reach those who are particularly vulnerable at the times when they are in greatest need.

KH: Added language to indicate this.

risk factors for suicide. A longitudinal analysis of annual data on suicides and foreclosures demonstrated that as the proportion of foreclosed properties increased in U.S. states, so did the state suicide rate, particularly among working-aged adults (Houle & Light, 2014). Another study of data from 16 U.S. states participating in the National Violent Death Reporting System found that suicides precipitated by home foreclosures and evictions increased more than 100% from 2005 (before the housing crisis began) to 2010 (after it had peaked; Fowler, Gladden, Vagi, Barnes, and Frazier (2015)). Most of these suicides occurred prior to the actual loss of the decedent's home. These findings suggest that integrating suicide prevention resources, messaging, and referrals into financial, foreclosure, and move-out planning and counseling services may help to prevent suicide.

## Strengthen Access to Mental Health Care

### Rationale

While most people with mental health problems do not attempt or die by suicide (Olfson, Gerhard, Huang, Crystal, & Stroup, 2015; Owens, 2002), ~~and the level of risk~~ conferred by ~~different types of mental illnesses differ~~ varies (Arsenault-Lapierre, Kim, & Turecki, 2004; E. C. Harris & Barraclough, 1997; Tyrer, Reed, & Crawford, 2015), previous research indicates that mental illness is an important risk factor for suicide (E. C. Harris & Barraclough, 1998; World Health Organization, 2014). Studies suggest that up to 90% of people who die by suicide may have had a mental ~~illness~~ or substance abuse problems at the time of their deaths (Arsenault-Lapierre et al., 2004; Cavanagh, Carson, Sharpe, & Lawrie, 2003; Isometsa, 2001). State-level suicide rates have also been found to be correlated with general mental health measures such as depression (Lang, 2013; Mark, Shern, Bagalman, & Cao, 2007). Findings from the National Comorbidity Survey indicate that relatively few people in the U.S. with mental health disorders receive treatment for those conditions (Kessler et al., 2005). Lack of access to mental health care is one of the contributing factors related to the underuse of mental health services (Cunningham, 2009). Identifying ways to improve access to timely, affordable, and quality mental health care for people in need is a critical component to suicide prevention (World Health Organization, 2014). Apart from the treatment benefits, it can also serve to normalize help-seeking behavior and increase the use of such services.

### Approaches

One approach to strengthening access to mental health care is through the provision of mental health coverage in health insurance policies.

- **Coverage of mental health conditions in health insurance policies.** Federal and state laws include provisions for equal coverage of mental health services in health insurance plans that is on par with coverage for other health concerns (i.e., mental health parity). Benefits and services covered include such things as the number of visits, co-pays, deductibles, inpatient/outpatient services, prescription drugs, and hospitalizations. If a state has a stronger mental health parity law than the federal parity law, then insurance plans regulated by the state must follow the state parity law. ~~Federal parity replaces the state law only in cases where the state law prevents the application of the federal parity law (e.g., includes coverage for some mental health conditions but not others).~~ If a state has a weaker parity law than the federal parity law (e.g., includes coverage for some mental health conditions but not others), then the federal parity law will replace the state law. Equal coverage does not necessarily imply good coverage as health insurance plans vary in the extent to which benefits and services are offered to address various health conditions. Rather it helps to ensure that mental health services are covered on par with other health concerns.

**Comment [A]:** From JM: I assume this means that different types of mental health problems pose different risks for suicide, but wasn't sure? May want to make the point more explicit

**KH:** Yes – added some language that I think helps to clarify this point.

**Comment [A]:** From TS: Isn't this including substance abuse disorder? It would be good to state this explicitly.

**Yes - Added.**

**Comment [A]:** From TS: I found this sentence confusing. Can you reword to simplify this.

From LLD: could say: "if a state has a weaker parity law than the federal parity law (e.g., includes coverage for some mental health conditions but not others), then the federal parity law will replace the state law."

**Thanks, Linda. Accepted your suggestion.**

### Potential Outcomes

- ~~Increased-Increases in~~ utilization of mental health services
- ~~Decreased-Reductions in~~ symptoms of mental illnesses
- ~~Decreased-Reductions in~~ rates of suicide attempts
- ~~Decreased-Reductions in~~ rates of suicide

### Evidence

There is evidence suggesting that coverage of mental health conditions in health insurance policies can reduce risk factors associated with suicide and may directly impact suicide rates.

- **Coverage of mental health conditions in health insurance policies.** The National Survey of Drug Use and Health is a nationally representative survey of the U.S. population that provides data on substance use, mental health conditions, and services utilization. Using data from this survey, K. M. Harris, Carpenter, and Bao (2006) found that 12 months after states enacted *mental health parity laws*, self-reported use of mental healthcare services significantly increased. Moreover, subsequent research by Lang (2013) examined state mental health laws and suicide rates between 1990 and 2004 and found that mental health parity laws, specifically, were associated with an approximate 5% reduction in suicide rates. This reduction, in the 29 states with parity laws, equated to the prevention of 592 suicides per year. Lang et. al (2013) estimated the cost of saving a life through such mandates as mental health parity by comparing the loss in wages attributable to the policy, via increased premiums, to the number of lives saved. Based on these calculations, the cost of saving one life was between a cost-savings of \$1.3-3.1 million per suicide prevented. However, this calculation did not take into account the saving associated with improved mental health among non-suicidal individuals, increases in productivity, or quality of life associated with increased mental health care. As such, this figure is considered the upper bounds on costs incurred and should be interpreted with caution (Lang, 2013).

**Comment [A]:** From TS: I don't think this is accurate. I was curious about this study and checked out the paper. I think they are saying that this is the cost incurred per suicide prevented. They go on to explain that this is the upper bound and does not reflect the benefits to non-suicidal individuals. Please confirm this. If you are going to include this then it will be important to explain it further.

## Create Protective Environments

### Rationale

Prevention efforts that focus not only on individual behavior change (e.g., help-seeking, treatment interventions) but on changes to the environment can increase the likelihood of positive behavioral and health outcomes (Haddon, 1980). Creating environments that address risk and protective factors where individuals live, work, and play, can help prevent suicide (Dahlberg & Krug, 2002; U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012). For example, rates of suicide and suicide attempts are elevated in certain occupational groups (Han et al., 2016; McIntosh et al., 2016), therefore, changes to the organizational culture in these occupations, by way of implementation of supportive policies or even physical modifications to the workplace environment, can change social norms, encourage help-seeking, and demonstrate that good health and mental health are valued and that stigma and other risk factors for suicide are not (K. L. Knox et al., 2010; National Action Alliance for Suicide Prevention Workplace Task Force, 2015). Similarly, modifying the characteristics of the environment to prevent harmful behavior such as access to lethal means can reduce suicide rates, particularly in times of crisis (Beautrais, Gibb, Fergusson, Horwood, & Larkin, 2009; A.E. Crosby, Espitia-Hardeman, Ortega, & Lozano, 2013; Kaplan et al., 2013; Miller, Warren, Hemenway, & Azrael, 2015; C. W. Runyan et al., 2016).

### Approaches

The current evidence suggests three **promising** **potential** approaches for creating environments that protect against suicide.

- **Reducing access to lethal means among persons at-risk of suicide.** Means of suicide such as firearms, hanging/suffocation, or jumping from heights provide little opportunity for rescue and, as such, have high case fatality rates (e.g., about 85% of people who use a firearm in a suicide attempt will die from the injury). Research also indicates that 1) the interval between thinking about and attempting suicide can be as short as 5 or 10 minutes (Deisenhammer et al., 2009; Simon et al., 2001) and 2) that people tend *not* to substitute a different method when a highly lethal method is unavailable or difficult to access (Hawton, 2007; Yip et al., 2012). Therefore, increasing the time interval between the thought and the suicide attempt, for example, by making it more difficult to access lethal means, can be lifesaving. The following are examples of approaches reducing access to lethal means for persons at-risk of suicide:
  - *Intervening at Suicide Hotspots.* Suicide hotspots, or places where suicides may take place relatively easily, include tall structures (e.g., bridges and cliffs), railway tracks, and isolated locations such as parks. Efforts to prevent suicide at these locations include

**Comment [A]:** From JM: The word promising has certain connotations when using it around evidence. You say later that the evidence around this strategy is some of the strongest for suicide. These two statements seem somewhat inconsistent. I would use a different word here then promising if you truly believe there is strong evidence.

From JH: suggest deleting the word "promising"

From LLD: since we don't want to infer that these are the only approaches for creating protective environments, I might be inclined to change the word "promising" to "potential" or "possible" or something along those lines.

KH: Thank you for the suggestions.

erecting barriers to prevent jumping and installing signs and telephones to encourage individuals who are considering suicide, to seek help (Cox et al., 2013).

- *Safe Storage Practices.* Safe storage of medications, firearms, and other household products can reduce the risk for suicide by separating individuals who may be vulnerable and/or impulsive from easy access to lethal means. Such practices may include education and counseling around storing firearms--locked in a secure place (e.g., in a gun safe or lock box), unloaded and separate from the ammunition--and keeping medicines in a locked cabinet or other secure location away from people who may be at risk or who have made prior attempts (Rowhani-Rahbar, Simonetti, & Rivara, 2016; C. W. Runyan et al., 2016).
- **Organizational policies and culture** that promote protective environments may be implemented in places of employment. Such policies and cultural values may promote prosocial behavior (e.g., asking for help), skill building, changing social norms, referral and access to helping services (e.g. mental health, substance abuse treatment, financial counseling), and encourage leadership support from the top down. Such policies and cultural shifts can positively impact organizational climate and morale and help prevent suicide and its related risk factors (e.g. depression, social isolation) (National Action Alliance for Suicide Prevention Workplace Task Force, 2015).
- **Community-based policies to reduce excessive alcohol use.** Research studies in the United States have found that greater alcohol availability is positively associated with alcohol-involved suicides (Escobedo & Ortiz, 2002; Giesbrecht et al., 2015). Policies to reduce excessive alcohol use broadly include zoning to limit alcohol outlet locations and density, taxes on alcohol, and bans on the sale of alcohol for individuals under the legal drinking age. These policies are important because acute alcohol use has been found to be associated with more than one-third of suicides and approximately 40% of suicide attempts (Cherpitel, Borges, & Wilcox, 2004).

### Potential Outcomes

- Increases in safe storage of means
- Reductions in suicide attempts
- Reductions in suicide deaths
- Increases in help-seeking
- Reductions in alcohol-related suicide deaths

### Evidence

The evidence for the effectiveness of preventing suicide by reducing access to lethal means ~~for person at-risk of suicide~~ and ~~other ways to~~ otherwise establishing protective environments for individuals at

risk of suicide is strong, particularly compared to existing evidence for other prevention strategies ~~is some of the strongest~~ in the field (Zalsman et al., 2016).

- **Reducing access to lethal means among persons at-risk of suicide.** A meta-analysis examining the impact of *suicide hotspot interventions* implemented in combination or in isolation, both in the U.S. and abroad, found associated reduced rates of suicide (Cox et al., 2013; Pirkis et al., 2015). For example, after erecting a barrier on the Jacques-Cartier bridge in Canada, the suicide rate from jumping from the bridge decreased from about 10 suicide deaths per year to about 3 deaths per year (Perron, Burrows, Fournier, Perron, & Ouellet, 2013). Moreover, the reduction in suicides by jumping was sustained even when all bridges and nearby jumping sites were considered, suggesting little to no displacement of suicides to other jumping sites (Perron et al., 2013). Further evidence for the effectiveness of bridge barriers was demonstrated by a study examining the impact of the *removal* of safety barriers from the Grafton Bridge in Auckland, New Zealand. After removal of the barrier, both the number and rate of suicide increased fivefold (Beautrais, 2001; Beautrais et al., 2009).

Another form of means reduction involves implementation of *safe storage practices*. In a case-control study of firearm-related events identified from 37 counties in Washington, Oregon, and Missouri, and from 5 trauma centers, Grossman et al. (2005) found that storing firearms unloaded, separate from ammunition, in a locked place or secured with a safety device was protective of suicide attempts among adolescents. Further, a recent systematic review of clinic and community-based education and counseling interventions suggested that the provision of safety devices significantly increased safe firearm storage practices compared to counseling alone or compared to the provision of economic incentives to acquire safety devices on one's own (Rowhani-Rahbar et al., 2016).

Another program, *The Emergency Department Counseling on Access to Lethal Means (ED CALM)*, trained psychiatric emergency clinicians in a large children's hospital to provide lethal means counseling and safe storage boxes to parents of patients under age 18 receiving care for suicidal behavior. In a pre-post quality improvement project, Runyan et al (2016) found that at post-test 76% (of the 55% of parents followed up, n=114) reported that all medications in the home were locked up as compared to fewer than 10% at the time of the initial emergency department visit. Among parents who indicated the presence of guns in the home at pre-test (i.e. 67%), all (100%) reported guns were currently locked up at post-test (C. W. Runyan et al., 2016).

- **Organizational policies and culture.** *Together for Life* is a workplace program of the Montreal Police Force implemented to address suicide among officers. Policy and program components were designed to foster an organizational culture that promoted mutual support and solidarity among all members of the Force. The program included training of supervisors, managers and

**Comment [A]:** From JM: Consistent with promising used earlier? Is it the strongest?

I think it is consistent with promising, but we changed that to potential. The interpretation from the paper states "no single strategy clearly stands above the others", so I would be hesitant to call it out as the strongest evidence, but it definitely may be for certain populations. Modified to simply indicate that it is strong.

all units to improve competencies in identifying suicidal risk and to improve use and awareness of existing resources. The program also included an education campaign to improve awareness and help-seeking (Mishara & Martin, 2012). Police suicides were tracked over 12 years and compared to rates in the control city of Quebec. The suicide rate in the intervention group decreased significantly by 78.9% to a rate of 6.4 suicides per 100,000 population per year compared to an 11% increase in the control city (29.0 per 100,000) (Mishara & Martin, 2012).

Another example of this approach is the *United States Air Force Suicide Prevention Program (AFSPP)*. AFSPP included 11 policy and education initiatives and was designed to change the culture of the Air Force surrounding suicide. The program uses leaders as role models and agents of change, establishes expectations for behavior related to awareness of suicide risk, develops population skills and knowledge (i.e., education and training), and investigates every suicide (i.e., outcomes measurement). The program represents a fundamental shift from viewing suicide and mental illness solely as medical problem and instead sees them as larger service-wide problems impacting the whole community (K. L. Knox, Litts, Talcott, Feig, & Caine, 2003). Using a time-series design to examine the impact of the AFSPP program on various violence-related outcomes, researchers found that the program was associated with a 33% relative risk reduction in suicide (K. L. Knox et al., 2003). The program was also associated with relative risk reductions in related outcomes including moderate and severe family violence (30% and 54%, respectively), homicide (51%), and accidental death (18%) (K. L. Knox et al., 2003). A longitudinal assessment of the program over the period 1981 to 2008 (16 years before the 1997 launch of the program and 11 years post-launch) found significantly lower rates of suicide after the program was launched than before (K. L. Knox et al., 2010). These effects were sustained over time, except in 2004, which the authors found was associated with less rigorous implementation in that year than in the other years (K. L. Knox et al., 2010).

- **Community-based policies to reduce excessive alcohol use.** While multiple policies to limit excessive use of alcohol exist, several studies on alcohol outlet *density*, specifically, suggest that measures to reduce alcohol outlet density can potentially reduce alcohol-involved suicides. Additionally, a longitudinal analysis of alcohol outlet density, suicide mortality, and hospitalizations for suicide attempts over 6 years in 581 California zip codes indicated that the density of bars, specifically, is related to suicide and suicide attempts, particularly in rural areas (Johnson, Gruenewald, & Remer, 2009).

## Rationale

Sociologist, Emile Durkheim theorized in 1897 that weak social bonds, i.e. lack of connectedness, are among the chief causes for suicidality (Durkheim, 1897/1951). *Connectedness* is the degree to which an individual or group of individuals are socially close, interrelated, or share resources with others (Centers for Disease Control and Prevention, 2009). Social connections can be formed within and between multiple levels of the social ecology (Dahlberg & Krug, 2002), for instance between individuals (e.g. peers, neighbors, co-workers), families, schools, neighborhoods, workplace, faith communities, cultural groups, and society as a whole. Related to connectedness, *social capital* refers to a sense of trust in one's community and neighborhood, social integration, and also the availability and participation in social organizations (Beyer, Layde, Hamberger, & Laud, 2015; Muennig, Cohen, Palmer, & Zhu, 2013). Many ecological cross-sectional and longitudinal studies have examined the impact of aspects of social capital on depression symptoms, depressive disorder, mental health more generally, and suicide. While the evidence is still being built, limited, existing studies suggest the pattern is towards a positive n-inverse association between social capital measured by social trust, community/ neighborhood engagement, and improved mental health. Connectedness and social capital together can serve to protect against suicidal behaviors by decreasing isolation, encouraging adaptive coping behaviors, increasing belongingness, personal value and worth all of which helps individuals to build resilience in the face of adversity. Connectedness can also provide individuals with better access to formal supports and resources, mobilize communities to meet the needs of its members and provide collective primary prevention activities to the community as a whole (Centers for Disease Control and Prevention, 2009).

## Approaches

Promoting connectedness among individuals and within communities through modeling peer norms and enhancing community engagement can protect against suicide.

- **Peer norm approaches** seek to normalize prosocial behaviors/protective factors for suicide such as help-seeking, reaching out and talking to trusted adults, and promote peer connectedness. These approaches typically target youth and are delivered in school settings but can also be implemented in community settings.

**Comment [A]:** From JM: Seems like a nuance you can delete from this paragraph. You don't really pick up on this later and it probably requires more explanation

**Comment [A]:** From JH: Awkward wording. Consider, while the evidence is limited, existing studies suggest...

**Comment [A]:** From JM: This implies that prosocial behavior is currently abnormal. Maybe promote is a better word?

From JH: suggest deleting "seek to normalize" and say "Peer norm approaches encourage prosocial behavior..."

**Comment [A]:** I prefer to keep it as normalize and took out prosocial behavior. We want to normalize help-seeking versus making it seem like a personal weakness.

- **Community engagement activities.** Community engagement is an aspect of social capital. Community engagement approaches may involve residents participating in a range of activities, including religious activities, community clean-up and greening activities, and physical exercise. These activities provide opportunities for residents to become more involved in the community and to connect with other community members, organizations, and resources, resulting in enhanced overall physical health, reduced stress, and decreased depressive symptoms, thereby reducing risk of suicide.

### Potential Outcomes

- Reductions in maladaptive coping attitudes and behaviors
- Increases in healthy coping attitudes and behaviors
- Increases in referrals for youth in distressed
- Increases help-seeking behaviors
- Increases in positive perceptions of adult support

### Evidence

Current evidence suggests that peer norm approaches and community engagement can reduce risk factors associated with suicidal behaviors.

- **Peer norm approaches.** Evaluations show that programs such as *Sources of Strength* can improve school norms and beliefs about suicide that are created and disseminated by student peers. In a randomized controlled trial of *Sources of Strength* conducted with 18 high-schools (6 metropolitan, 12 rural), Wyman et al. (2010) found that the program improved peer leaders' adaptive norms regarding suicide among peer leaders, their connectedness to adults, and school engagement. Peer leaders were also more likely than controls to refer a suicidal friend to an adult. ~~Among students, the intervention~~ For students, the program resulted in increased perceptions of adult support for suicidal youths, particularly among those with a history of suicidal ideation, and the acceptability of help-seeking behaviors seeking help. Perception of adult support increased most in students with a history of suicidal ideation. Finally, trained peer leaders also reported a greater decrease in maladaptive coping attitudes compared with untrained leaders (Wyman et al., 2010). More evaluation research is needed to examine whether these improvements in factors that protect against suicidal behavior translate into reduced suicidal behavior and suicide.
- **Community engagement activities.** A vacant lot greening initiative was undertaken in Philadelphia between 1999 and 2008. Local residents and community members worked together to green 4,436 lots (or 7.8 million square feet) in 4 areas of the city. Researchers found significant associated reductions in community residents' self-reported level of stress, which is a risk factor

**Comment [A]:** From JH: Cite findings from Let's Connect intervention program? While the intervention didn't significantly reduce suicidal behavior, there were significant improvements in connectedness (a protective factor for suicide).

KH: This is a great thought. We have quite a few programs that didn't reduce suicidal behavior, but do impact related RFs, so we're trying to stray from them and focus on those that impacted suicide and attempts or have a greater amount of evidence/more evaluations behind them.

**Comment [A]:** From TS: Is there any evidence on outcomes more proximal to suicide? Did they look for any and not find them? It is important to describe relevant null effects when they were found.

KH: They did not look at more proximal outcomes, but SOS is currently undergoing a 6-year evaluation funded by NIMH to examine impact, hopefully with suicidal behaviors being one of the outcomes they're measuring.

for suicide, stress levels and engagement in more physical exercise, a protective factor for suicide, than residents in control vacant lot areas. Other benefits included reductions in firearm assaults and vandalism (Branas et al., 2011).

**Comment [A]:** From JM: Not seeing strong evidence here. Are you suggesting that this affects documented risk factors for suicide by reducing stress and increasing physical exercise? I would like to see a stronger evidence statement here.

From LLD: you might want to incorporate a phrase in the statement along the lines of "which are risk factors for suicide"

KH: Added the qualifier you suggested, Linda.

**Comment [A]:** From TS: They had a follow up paper in 2013 that showed intervention sites felt significantly safer. The effects on crimes was encouraging but not significant. It seems important to mention this too.

From LLD: not sure I agree with Tom's last point about mentioning the nonsignificant effect on crime.

**Comment [A]:** From LLD: the word "either" here implies another comparative clause; should the word "or" be inserted before the word "modeling"? May want to just delete the word "either"

KH: Added.

## Teach Coping and Problem-Solving Skills

### Rationale

Building life skills prepares individuals to successfully tackle every day challenges and adapt to stress and adversity. Life skills encompasses many concepts, but most often include coping and problem-solving skills, conflict resolution, and critical thinking. Life skills are important in shielding individuals from suicidal behaviors (World Health Organization, 2014). Suicide prevention programs that focus on life and social skills training are drawn from social cognitive theories (Bandura, 1986), surmising that suicidal behavior is attributed to ~~either~~ direct learning, modeling, ~~and or~~ environmental and individual (e.g. hopelessness) characteristics. The literature linking life skills and suicide is robust. The inability to employ adequate strategies to cope with immediate stressors or identify and find solutions for problems has been characterized among suicide attempters (Pollock & Williams, 2004). Treatments that include bolstering skills (Goldsmith, Pellmar, Kleinman, & Bunney, 2002) and include problem-solving techniques (Ghahramanlou-Holloway, Bhar, Brown, Olsen, & Beck, 2012; Townsend et al., 2001) appear to reduce suicidal ideation and attempts more effectively. Prevention programs focused on teaching these skills target youth, parents and families and have been used with both universal and at-risk populations. While many do not target suicidal behaviors directly, these programs strive to train youth and parents in important life skills to offset the underlying vulnerabilities that contribute to engaging in high-risk behaviors early in life.

### Approaches

Current evidence provides support for the following two approaches:

- **Social emotional learning programs** focus on developing and strengthening communication and problem-solving skills, emotion regulation, conflict resolution, help seeking and coping skills. These approaches address a range of risk and protective factors for suicidal behavior. They provide children and youth with skills to resolve problems in relationships, school, and with peers, and help youth to address other negative influences (e.g., substance use) associated with suicide. These approaches are typically delivered to all students in a particular grade or school, although some programs also focus on groups of students considered to be at high risk for suicide. Opportunities to practice and reinforce skills are an important part of programs that work (Herman, Borden, Reinke, & Webster-Stratton, 2011).

- **Parenting skill and family relationship programs** are designed to strengthen parenting skills, enhance positive parent-child interactions, and improve children's behavioral and emotional skills and abilities. Several parenting and family relationship programs have been shown in rigorous evaluations to improve resilience and reduce risk factors for various behaviors, including ones closely related to suicide, such as depression, internalizing behaviors, and substance abuse (M. S. Knox, Burkhart, & Hunter, 2010).

### Potential Outcomes

- Reductions in suicide attempts and suicide ideation
- Improvements in Enhanced knowledge of risk and protective factors associated with suicide
- Reductions in suicide risk behaviors (i.e., depression, anxiety, conduct problems, substance abuse)
- Improvements in and normalize help-seeking behavior
- Improvements Enhance in social competence and emotional regulation skills
- Improvements Enhance in problem-solving and conflict management skills

### Evidence

There are several programs with evidence that support teaching social, emotional and parenting skills to reduce suicidal behaviors and associated risk factors.

- **Social emotional learning programs.** The *Youth Aware of Mental Health Program (YAM)* is a program developed for teenagers that uses interactive dialogue and role-playing to teach adolescents about the risk and protective factors associated with suicide (including knowledge about depression and anxiety) and enhances their problem-solving skills for dealing with adverse life events, stress, school and other problems. The program includes 3 hours of role-play sessions and interactive workshops combined with a booklet that students can keep, educational posters displayed in classroom, and interactive lectures about mental health at the beginning and end of the program (Wasserman et al., 2014). In a cluster-randomized controlled trial of YAM conducted across 10 European Union countries and 168 schools, students aged 14-16 participating in the YAM program were significantly less likely to have an incident suicide attempt (OR 0.45, 95% CI 0.24–0.85;  $p=0.014$ ) attempt suicide and have severe suicidal ideation (0.50, 0.27–0.92;  $p=0.025$ ) at the 12-month follow-up compared to the control group which did not participate in an intervention. Overall, the relative risk of youth suicide attempts among the YAM group was reduced by over 50%, indicating demonstrating that out of 1000 students, five attempted suicide in the YAM group compared to 11 in the control group. Additionally, related to severe suicide ideation, in the

**Comment [A]:** I think this should be this reference – 2015:

Wasserman, D., Hoven, C. W., Wasserman, C., Wall, M., Eisenberg, B., Hadlaczky, G., ... & Bobes, J. (2015). School-based suicide prevention programmes: the SEYLE cluster-randomised, controlled trial *The Lancet*, 385(9977), 1536-1544

**Comment [A]:** From JH: Report ages (compare to SOS below)

**Comment [A]:** From JH: Suggest translating OR and 95% CI for wider audience.

From LLD: agree; this is too technical for a wider audience. See Tom's suggestion below.

Revised accordingly

**Comment [A]:** From JH: state if the control group received any kind of intervention

Added

YAM group absolute risk fell by 0.50% and relative risk fell by 49.6% (Wasserman et al., 2014).

Comment [A]: From JH: significant?

Comment [A]: From TS: The Lancet paper has a 2015 publication date.

The authors provide the absolute and RR for suicide attempts too and they give a clear way of thinking about this – i.e., for RR “Of 1000 pupils, 11 attempted suicide in the control group vs five attempts in YAM”

It might be worth using the attempt example so you can provide this explanation.

Revised.

Comment [A]: From JH: significant? Effect size/magnitude of reduction?

Comment [A]: From JH: define control condition

Comment [A]: From JH: significant?

Comment [A]: From JH: Lower-risk? Do you mean students with no prior reported history of suicide attempts?

Comment [A]: From LLD: Jeff had questions about what is meant by upstream. You are referring to primary prevention but some of the other

Comment [A]: From JH: compared to?

Added.

Comment [A]: From JH: Suggest stating clearly there are two separate cohorts of students receiving the intervention. How do these cohorts differ (time, location)?

Comment [A]: From TS: It is important to help the reader to understand that this study looked at the suicidal ideation when the first graders were age 19-21. This is

Comment [A]: From JH: Is this the authors' comment or your interpretation of the data? Please clarify.

*Signs of Suicide (SOS)* is another school-based prevention program for students aged 13-17. The program includes guided classroom discussions about suicide and depression. As part of the program, students are screened for depression and suicide risk and referred for professional help as indicated. The program is designed to increase knowledge about suicide and risk factors associated with suicidal behavior as well as improve and normalize help-seeking behavior (Schilling, Aseltine, & James, 2016). In a randomized controlled trial, *SOS* was shown to reduce self-reported suicide attempts at 3-months post intervention among participating students compared to control students. The *SOS* program also increased students' knowledge of how to get help for themselves or friends for depression and/or suicidal thoughts, and favorable attitudes toward help-seeking. *SOS* participants with a lifetime history of suicide attempt were also less likely to report planning a suicide in the 3 months following the program compared to lower-risk participants (Schilling et al., 2016).

Finally, the *Good Behavior Game (GBG)* is a classroom-based program for elementary school children aged 6-10; ~~it represents an example of upstream suicide prevention programming~~. The program uses a team-based behavior management strategy that promotes good behavior by setting clear expectations for good behavior and consequences for maladaptive behavior. The goal of the *GBG* is to create an integrated classroom social system that is supportive of all children being able to learn with little aggressive or disruptive behavior (Wilcox et al., 2008). Two cohorts of youths participated in the program in 1985-85 and 1986-86 school years when they were in the first and second grades. A number of proximal and distal outcomes were assessed among the two cohorts over time. With respect to distal suicide-related outcomes, an outcome evaluation of the GBG indicated that first-graders assigned individuals in the first cohort who were assigned to participate in the GBG when they were in the first grade reported half the adjusted odds of suicidal ideation and suicide attempts when assessed approximately 15 years later, between the ages of 19 to 21, compared to peers who had been in a standard classroom setting. The beneficial effect of the program was consistent for suicidal ideation regardless of whether baseline covariates were included. The *GBG* effect on attempts was less robust in some adjusted models including caregiver mental health. In the second cohort of *GBG* students, neither suicidal ideation nor suicide attempts were significantly different between *GBG* and the control interventions (Wilcox et al., 2008). ~~this~~ The authors surmise this finding likely arose due to the lack of implementation fidelity and pointed to the need for *GBG* to be delivered with precision, consistency, and teacher support. *GBG* was also found to be associated with reduced risk of later substance abuse, a risk factor for suicide (Kellam et al., 2008).

- **Parenting skill and family relationship programs.** Parenting and family skills training approaches have shown promising impacts in preventing key risk factors associated with suicide. For example, the *Incredible Years (IY)* is a comprehensive group training program for parents, teachers and children designed to reduce conduct and substance abuse problems, two important suicide risk factors, in youth by improving protective factors such as responsive and positive parent-teacher-child interactions and relationships, emotion self-regulation and social competence (all protective factors for suicide) (Herman et al., 2011). The program includes 9- 20 sessions offered in community-based settings (e.g., religious, recreation centers, mental health treatment centers, and hospitals). Several studies have demonstrated the effect of the *IY* program on reducing internalizing symptoms, such as anxiety and depression, and child conduct problems (C. H. Webster-Stratton, Reid, & Beauchaine, 2011; Webster-Stratton, Jamila Reid, & Stoolmiller, 2008). The program is also associated with improved problem-solving and conflict management; these skills were maintained at 1-year follow-up (Reid, Webster-Stratton, & Hammond, 2003; C. Webster-Stratton & Hammond, 1997; C. Webster-Stratton, Reid, & Hammond, 2001). The program demonstrated greater benefits as the dosage of the intervention increased (Herman et al., 2011).

Additionally, *Strengthening Families 10-14* is a program that involves sessions between parents, youth, and family with the goal of improving parents' skills for disciplining, managing emotions and conflict, and communicating with their children; promoting youths' interpersonal and problem-solving skills; and creating family activities to build cohesion and positive parent-child interactions. The premise of the program is that developing these skills for both parents and children will reduce internalizing behavior and adolescent substance abuse, two important risk factors for suicide (Spoth, Gyll, & Day, 2002). *Strengthening Families* has been shown to significantly decrease externalizing behaviors, such as aggression, alcohol use, and drug use among youth participants (and, as well as reductions in depression, alcohol use, and drug use among participating families (Spoth et al., 2002).

**Comment [A]:** From JH: significant? Also please define externalizing behaviors.

KH Added

**Comment [A]:** From TS: This transition seems off.

KH: edited.

## Identify and Support People At-Risk

### Rationale

In order to decrease suicide, attention to people at increased ~~or high-risk~~, for example people with prior suicide attempts, is necessary, as these individuals tend to experience suicidal behavior at higher than average rates. These vulnerable or disadvantaged populations include, but are not limited to, individuals with lower socio-economic status or who are living with a mental health problem; people who have attempted suicide previously; individuals who are institutionalized, have been victims of violence, or are homeless; and members of certain racial and ethnic minority groups. Supporting these vulnerable groups requires proactive case finding along with access to, and retention in, mental health services. Finding effective ways of identifying at-risk or vulnerable groups, customizing services to make them accessible and engaged in care remain key challenges. For example, simply improving services does not guarantee that those services will be used by those most in need of them, nor will it necessarily increase the number of people who follow treatments that are recommended. People who are disadvantaged face social and economic issues that may adversely affect their ability to respond to the treatments or advice that are offered.

**Comment [A]:** From TS: This seems awkward as written. It might be better to say "...attention to people with specific vulnerabilities..."

**Comment [A]:** I'm not sure about 'specific vulnerabilities' terminology. I think people are much more familiar with something like this.

### Approaches

The following three approaches focus on identifying and supporting people at increased risk.

- **Gatekeeper training** is designed to train teachers, coaches, providers and others in the community to identify people who may be at risk of suicide and to respond effectively, including facilitating treatment seeking and support services. Gatekeeper training is typically implemented in schools to identify at-risk youth and within health care settings to identify adults (and youth).
- **Screening combined with care management and overall continuity of care** has been used in primary care and behavioral health care settings to assure that people who may be at high-risk of suicide are identified and receive ongoing treatment as needed, particularly after inpatient discharge and other transitions within the healthcare system so they don't 'slip through the cracks'. These approaches typically employ screening for depression and/or suicide combined with collaborative treatment planning between patients and their providers and patient follow-up.
- **Crisis intervention.** These approaches provide support and referral services, typically by connecting a person in crisis (or a friend or family member of someone at-risk) to trained volunteers or professional staff via telephone hotline, online chat, or text messaging. Crisis intervention approaches are intended to impact key risk factors for suicide, including feelings of

depression, hopelessness, and subsequent mental health care utilization. Like means reduction, crisis interventions can put space or time between an individual who may be considering suicide and harmful behavior.

### Potential Outcomes

- Reductions in suicide attempts
- Reductions in suicide deaths
- ~~Increased-Increases in~~ identification of individuals at-risk for suicidal behavior
- ~~Increased-Increases in~~ at-risk individuals in treatment
- ~~Increased-Increases in~~ community members trained to identify at-risk individuals
- ~~Increased-Increases in~~ referrals for health care

### Evidence

~~Identifying people at risk of suicide can positively impact both suicide risk factors as well as suicide mortality, however sustained implementation of programs and practices appears critical. Among people who identify themselves through calls to suicide hotlines, preliminary evidence finds reductions in suicide risk factors. There is evidence that gatekeeper–successful in reducing suicides–but the efforts must be The number of studies evaluating crisis intervention services is limited, but–decreased suicidal thoughts and behavior.~~

- **Gatekeeper training.** One example of gatekeeper training is the *Mental Health First Aid (MHFA)* program. This program is designed for the lay public and consists of three weekly sessions of three hours each. Participants learn the symptoms of people in mental health crises and/or in the early stages of mental health problems (i.e., those experiencing suicidal thoughts and behavior, acute stress reaction, panic attacks and acute psychotic behavior, and depression, anxiety, and psychotic disorders), possible risk factors, and where and how to get ~~evidence-based effective~~ help (Kitchener & Jorm, 2004). In a randomized controlled trial of 301 participants of MHFA, the ~~intervention group, compared to the wait-listed control group,~~ reported at 5 months follow-up, significantly ~~greater feelings of confidence~~ in helping someone (74.5% vs. 57.4%,  $p<.001$ ), greater likelihood of encouraging people to seek professional help (29.4% vs. 16.8%,  $p<.007$ ), improved agreement with health professionals about treatments ( $p<.036$ ), and decreased stigmatizing attitudes towards mental illness ( $p<.02$ ). Additionally, the intervention resulted in improved ~~overall~~ mental health of the participants themselves ( $p<.035$ ). ~~However, the percent who provided some or a lot of help did not differ between groups (~~ (Kitchener & Jorm, 2004). Additional research rigorously evaluating MHFA for its impact on intervention recipients' suicidal behavior is needed (Kitchener & Jorm, 2006).

**Comment [A]:** From LLD: suggest shortening this introductory statement about the evidence and making it consistent with the other sections. If you need to provide caveats, then you might want to take a look at the YV TP for example wording.

**Comment [A]:** From TS: Add cites here. Also this wording is awkward because it could be read as suggesting that those who chose to use the hotline are different from others at risk who did not. Maybe you could add the follow up period to the end – they have decrease suicidal thoughts and behavior at xx

**Comment [A]:** From LLD: wording is a bit awkward here

**Comment [A]:** From JH: compared to?

**Comment [A]:** From JH: significant? Is it possible to report magnitude of intervention effects?

**Comment [A]:** From JH: Overall mental health or specific facets (e.g., depression, etc.)? Please clarify

Gatekeeper training has also been a primary part of all *Garret Lee Smith (GLS) Suicide Prevention Program* which is in place in 49 states and 48 tribes. A multi-site evaluation assessed the impact of community gatekeeper training on suicide attempts and deaths by comparing the change in suicide rates and nonfatal suicidal behavior among young people aged 10-24 in counties implementing GLS trainings, with the trajectory observed in similar counties that did not implement these trainings. Counties that implemented GLS trainings had significantly lower youth suicide rates one year following the training implementation (Walrath, Garraza, Reid, Goldston, & McKeon, 2015). This finding equates to a decrease of 1 suicide death per 100,000 among youth ages 10 to 24, or the prevention of approximately 237 deaths in the age group, between 2007 and 2010. Counties implementing GLS program activities, including gatekeeper training, also had significantly lower suicide attempt rates among youth ages 16 to 23 in the year following implementation of the GLS program than did similar counties that did not implement GLS activities (4.9 fewer attempts per 1000 youths; (Godoy Garraza, Walrath, Goldston, Reid, & McKeon, 2015)). More than 79,000 suicide attempts may have been prevented during the period examined, following implementation of the GLS program.

- **Screening combined with care management and overall continuity of care.** The Henry Ford healthcare system is a large health maintenance organization (HMO) in the state of Michigan. Henry Ford's Perfect Depression Care program was the pre-cursor to what is now called Zero Suicide, and its overall goal was to eliminate suicide among its members. More broadly, the aim was to redesign delivery of depression care to achieve "breakthrough improvement" in quality and safety by focusing on six aims: effectiveness, safety, patient centeredness, timeliness, efficiency, and equity among patients. The program screened and assessed each patient for suicide risk and implemented coordinated continuous follow-up care system wide (C. E. Coffey, 2006). An examination of the impact of the program found that there was a dramatic and statistically significant decrease in the rate of suicide between the baseline years, 1999 and 2000, prior to the intervention to the intervention years, 2002-2009. During this time period, the suicide rate fell by 82% (C. E. Coffey, 2006; C. E. Coffey, Coffey, & Ahmedani, 2013). Further, among HMO members who received mental health specialty services, the suicide rate decreased from 110.3/100,000 in 1999 to 47.6/100,000 in 2010 (p<.04) with a mean of 36.2/100,000 over the time period. Additionally, for those HMO members who accessed only general medical services as opposed to specialty mental health services, the suicide rate increased from 2.7/100,000 to 5.6/100,000 (p<.01). Similarly, in the state of Michigan, rates of suicide in the general population increased over the period from 9.8/100,000 to 12.5/100,000 (p<.001) (M. Coffey, Coffey, & Ahmedani, 2015).

**Comment [A]:** From JM: I think you need to provide a little more context on Henry Ford so the readers understands in what kind of population the reductions were experienced. I assume from the end that Henry Ford is some sort of HMO, but just a little more information would help clarify this description to readers.

**Comment [A]:** From JH: how much?

- Crisis intervention.** Suicide prevention hotlines are one way to provide crisis intervention. In an evaluation of the effectiveness of the *National Suicide Prevention Lifeline (NSPL)* to prevent suicide, 1,085 suicidal individuals who called the hotline completed a standard risk assessment for suicide, and 380 of those completed a follow-up assessment between 1 and 52 days (mean=13.5 days) after the initial assessment. Researchers found that over half of the initial sample were seriously considering suicide when they called, and they had a plan for their suicide. Researchers also found that among follow-up participants, there was a significant decrease in psychological pain ( $F=52.8, p<.001$ ), hopelessness ( $F=47.8, p<.001$ ) and intent to die ( $F=7.57, p<.01$ ) between initiation of the call (time 1) to follow-up (time 3). Between time 2 (end of the call) to time 3, the effect remained for psychological pain ( $F=14.1, p<.001$ ) and hopelessness ( $F=17.03, p<.001$ ) but was not significant for intent to die. (Gould, Kalafat, Harrismunfakh, & Kleinman, 2007).

In another study, this time employing a randomized controlled trial, Gould, Cross, Pisani, Munfakh, and Kleinman (2013) assessed the impact of the *Applied Suicide Intervention Skills Training (ASIST)*, a widely implemented training program that helps hotline counselors, emergency workers, and other gatekeepers to identify and connect with suicidal individuals, understand their reasoning for living and dying, and assist with safely connecting those in need to available resources. The training was evaluated across the NSPL network of hotlines over the period 2008-2009. Using data from 1,410 suicidal individuals who called 17 Lifeline centers, researchers found that compared to callers who spoke to counselors that received the usual care training, individuals who spoke with counselors without training in ASIST were significantly more likely to feel depressed ( $OR=1.31 (1.01, 1.71)$ ), suicidal ( $OR=1.74 (1.39, 2.18)$ ), more overwhelmed ( $OR=1.46 (1.18, 1.82)$ , and less hopeful ( $1.35 (1.04, 1.77)$ ) by the end of their call to the hotline compared to those with training in ASIST. Counselors trained in ASIST were also more skilled at keeping callers on the phone longer and establishing a connection with them. However, training in ASIST did not result in more comprehensive suicide risk assessments than usual care training (Gould et al., 2013).

**Comment [A]:** From JH: Report magnitude of decrease?

**Comment [A]:** This is really the best I can do. Not sure if you want this level of detail however.

**Comment [A]:** To be consistent with above I added some measures of association.

## Intervene to Lessen Harms and Prevent Future Risk

### Rationale

Individuals who have experienced mental health challenges, suicidal ideation, who have made suicide attempts or engaged in non-suicidal self-injury are at increased risk of suicide (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012). Risk of suicide can also increase among those who have lost a friend, family member, co-worker, or other acquaintance to suicide (Pitman, Osborn, King, & Erlangsen, 2014). Exposure to sensationalized or uninformed reporting regarding on suicide may heighten the risk of suicide among vulnerable individuals and can inadvertently contribute to suicide contagion (Etzersdorfer & Sonneck, 1998; Niederkrotenthaler & Sonneck, 2007).

### Approaches

~~A broad array of a~~The four approaches included here to lesson harms and reduce future risk of suicide among those at increased risk focus on providing appropriate mental healthcare, continuity of care, caring for the bereaved, and providing safe messaging around suicide. include the provision of mental health care and improved continuity of care, improving linkage to care through active post-discharge planning and follow-up that decreases barriers to ongoing therapeutic support, increasing connectedness to supportive others, addressing bereavement, and framing communications to emphasize resilience, decrease negative affect, and to prevent contagion.

- **Treatment for people at-risk of suicide** typically includes various forms of psychotherapy delivered by licensed providers to help individuals with mental health problems and other risk factors for suicide with problem-solving, impulsivity and emotion regulation. Treatment usually takes place in a one on one or group format between patients and clinicians in mental healthcare settings and can vary in duration from several weeks to ongoing therapy for years in some cases.
- **Treatment to prevent re-attempts.** These approaches typically include follow-up contact and use diverse modalities (e.g., home visits, mail, telephone, e-mail) to engage recent suicide attempt survivors in continued treatment to prevent re-attempts. Treatment may focus on improved coping skills, mindfulness, and other emotional regulation skills, and may include case management home visits to increase adherence to treatment and continuity of care; and one-on-one interpersonal therapy and/or group therapy. Approaches that engage and connect attempters to peers and providers are especially important because many attempters do not present to aftercare; 12%-25% reattempt within a year, and 3%-9% of attempt survivors die by suicide within 1 to 5 years of their initial attempt (Inagaki et al., 2015)
- **Postvention** approaches are implemented *after* a suicide has taken place and may include debriefing sessions, counseling, and/or bereavement support groups for surviving friends and

**Comment [A]:** From LLD: simplify statement and make it consistent with the other introductory statements about approaches. You may also want to take a look at the introductory statements to this section in the other TPs.

**KH: edited.**

**Comment [A]:** From LLD: Suggest fleshing this description out a bit. You may want to mention how these are typically delivered (e.g., one on one or group formats; typical number of sessions, location, etc.).

Included some of this info. I don't think there's a "typical" number of sessions, as it seems to vary across treatment settings.

family members/loved ones. These programs have not typically been evaluated for their impact on suicide or suicidal behavior but may reduce survivors' guilt, feelings of depression, and complicated grief (Szumilas & Kutcher, 2011).

- **Safe messaging following a suicide.** The manner in which information on a recent suicide is communicated to the public (e.g. school assemblies, mass media, social media) can heighten the risk of suicide among vulnerable individuals and can inadvertently contribute to suicide contagion. Therefore, responsible and safe reporting may help prevent suicide and suicide contagion.

**Comment [A]:** From JH: add something about contagion?

KH: added

### Potential Outcomes

- Reductions in mental health-related sequelae
- Increases in connectedness
- Improvements in coping skills
- Improvements in messaging following suicide
- Reductions in re-attempts
- Reductions in contagion effects related to suicide

### Evidence

The evidence addressing strategies to lesson harm and prevent future risk of suicide includes the evaluation of effects of specific approaches on risk and protective factors as well as suicide-related mortality. However, because the evaluation of suicide-related mortality requires large sample sizes and extended follow-up, much of the evidence in this area primarily focuses on risk and protective factors.

- **Treatment for people at-risk of suicide.** There are a number of treatments with evidence of impact on risk and protective factors for suicide. One example is the *Improving Mood – Promoting Access to Collaborative Treatment (IMPACT)* program. *IMPACT* aims to prevent suicide among older primary care patients by reducing suicide ideation and depression in primary care settings. It facilitates the development of a therapeutic alliance, a personalized treatment plan that includes patient preferences, as well as proactive follow-up (biweekly during an acute phase and monthly during continuation phase) by a depression care manager (Hunkeler et al., 2006). The program has been shown to significantly improve quality of life, and to reduce functional impairment, depression and suicidal ideation over 24-months of follow-up (Hunkeler et al., 2006; Unutzer et al., 2006) relative to patients who received care as usual.

Another example is *Collaborative Assessment and Management of Suicidality (CAMS)*, which is a therapeutic approach for suicide-specific assessment and treatment of patient's suicide risk. This flexible approach can be used across treatment settings and clinician theoretical orientations and involves the clinician and patient working together in an interactive assessment process to develop patient-specific treatment plans. CAMS sessions are collaborative and involve constant patient input about what is and is not working with the ultimate goal of enhancing the therapeutic alliance and increasing treatment motivation in the suicidal patient. CAMS been tested and supported in 6 correlational studies (Jobes, 2012), in a variety of inpatient and outpatient settings and in one RCT with several additional RCTs under way. CAMS has been associated with significant improvements in suicidal ideation, overall symptom distress, and feelings of hopelessness at 12 month follow-up among a community-based sample of suicidal outpatients. (Comtois et al., 2011).

Other examples include *Dialectical Behavioral Therapy (DBT)* and *Attachment-Based Family Therapy (ABFT)*. DBT is a multicomponent therapy for individuals at high risk for suicide and who may struggle with impulsivity and emotional regulation. The components of DBT include individual therapy, group skills training, between-session telephone coaching and a therapist consultation team. In a randomized controlled trial of women with recent suicidal or self-injurious behavior, those receiving DBT were half as likely to make a suicide attempt at two-year follow-up than women receiving community treatment (23% vs 46%), required less hospitalization for suicide ideation, and had lower medical risk across all suicide attempts and self-injurious acts combined (Linehan et al., 2006).

ABFT is a program for adolescents aged 12-18 and is designed to treat clinically diagnosed major depressive disorder, eliminate suicidal ideation, and reduce dispositional anxiety (Diamond et al., 2010). A randomized controlled trial of ABFT found that suicidal adolescents assigned to ABFT experienced significantly greater improvement in suicidal ideation over 24 weeks of follow-up than did adolescents assigned to enhanced usual care. Additionally, a significantly higher percentage of ABFT participants reported no suicidal ideation in the week prior to assessment at 12 weeks than did adolescents receiving enhanced usual care (69.2% vs. 34.6%) and at 24 weeks (82.1% vs. 46.2%) (Diamond et al., 2010).

- **Treatment to prevent re-attempts.** Several strategies that aim to prevent re-attempts have demonstrated impact on reducing suicidal behavior. For example, *Emergency Department Brief Intervention with Follow-up Visits* is a program that involves a one-hour discharge information session that addresses suicidal behavior, distress, risk and protective factors, alternatives to suicidal behavior, and referral options, combined with nine follow-up contacts over 18 months (at 1, 2, 4, 7, 11 weeks and 4, 6, 12, 18 months). Follow-up contacts are either conducted by phone or through home visits according to a specific time line for up to 18-months. A randomized

Comment [A]: From TS: I think a word is missing – "patient input"?

Added.

controlled trial that enrolled suicide attempters from eight hospital emergency departments in five culturally different countries (Brazil, India, Sri Lanka, Iran, and China) sites found that a brief intervention combined with 9 follow-up visits over 18-months was associated with significantly fewer deaths from suicide relative to a treatment-as-usual group (0.2% versus 2.2%, respectively) (Fleischmann et al., 2008).

Another example of treatment to prevent re-attempts involves *active follow-up contact approaches* such as postcards, letters, and telephone calls intended to increase a patient's sense of connectedness with health care providers and decrease isolation. These approaches include expression of care and support and typically invite patients to reconnect with their provider. Contacts are made periodically (e.g., monthly or every few months in the first 12 months post-discharge with some programs continuing contact for two or more years). In a meta-analysis conducted by Inagaki et al. (2015), interventions to prevent repeat suicidal behavior in patients admitted to an emergency department for suicide attempt were found to reduce reattempts by approximately 17% for up to 12 months post-discharge; however, the long-term effects of these approaches over periods of time longer than one year on reattempts has not yet been demonstrated. Also, because the number of trials and associated sample sizes included in this meta-analysis were small, it was not possible to determine the effect of active contact and follow-up approaches on death by suicide. In a randomized controlled trial of the post-crisis suicide prevention long-term follow-up contact approach, Motto and Bostrom (2001) found that patients who refused ongoing care but who were randomized to be contacted by letter four times per year had a lower rate of suicide over two years of follow-up than did patients in the control group who received no further contact. Other studies have also shown post-crisis letters and coping cards to be protective against suicide ideation and attempts (Hassanian-Moghaddam, Sarjami, Kolahi, & Carter, 2011; Wang et al., 2016).

Finally, *Cognitive Behavior Therapy for Suicide Prevention (CBT-SP)* is an example of a therapeutic approach to prevent re-attempts. It uses a risk-reduction, relapse prevention approach that includes an analysis of proximal risk factors and stressors (e.g., relationship problems, school or work-related difficulties) leading up to and following the suicidal event; safety plan development; skill building; and psychoeducation. CBT-SP also has family skill modules focused on family support and communication patterns as well as improving the family's problem solving skills. A randomized controlled trial of CBT-SP found that 10-session outpatient cognitive therapy designed to prevent repeat suicide attempts resulted in a 50% reduction in the likelihood of a suicide reattempt among adults who had been admitted to an emergency department for a suicide attempt relative to treatment as usual (Brown et al., 2005).

**Comment [A]:** From JH: Unclear. According to the article, this program was evaluated in five countries. Please state the countries. Thnx.

Added.

**Comment [A]:** From JH: Define (follow-ups greater than 1 year)

Revised.

**Comment [A]:** From JH: Define

KH: Defined later in the sentence - contact 4x/yr, 2 years of follow up.

- Postvention** programs are implemented with the goal of providing support to survivors of others' suicide to reduce their own risk of suicide. One example of a postvention program, *StandBy Response Service (StandBy)*, provides clients with face-to-face outreach and telephone support through a professional crisis response team. Site coordinators develop customized case management plans, referring clients to other existing community services matched to their needs (Visser, Comans, & Scuffham, 2014). In a study by Visser et al. (2014), *StandBy* clients were significantly less likely to be at high risk for suicidality than a suicide bereaved comparison group who had not had contact with the *StandBy* program (48% and 64% respectively). Additionally, research suggests that active postvention approaches in which outreach to suicide survivors occurs at the scene of a suicide is associated with intake into treatment sooner, greater attendance at support group meetings, and attendance at more meetings compared to passive postvention (versus passive approaches where survivors self-refer for services) (J. Cerel & Campbell, 2008).
- Safe messaging following a suicide.** Safe messaging after a suicide can help assure that reporting of the event is done in such a way to reduce risk to consumers of news media and other messaging who may be particularly vulnerable. One way to ensure safe messaging following a suicide is to encourage that reporters adhere to *Recommendations for Reporting on Suicide* (<http://www.reportingonsuicide.org>). Reports that are both inclusive of suicide prevention messages, stories of hope and resilience, risk and protective factors, and links to helping resources (e.g., hotline) and that avoid sensationalizing events or reducing suicide to one cause can help reduce the likelihood of suicide contagion. The most compelling evidence supporting the effect of *recommendations for reporting on suicide* on reduction in suicides comes from Austria. After a sharp increase in suicides on the Viennese subway, media guidelines were introduced and an interrupted time series design was used to evaluate the national impact of the guidelines on subsequent suicides. Changes in the quality and quantity of media reporting resulted in a *nationwide* significant reduction of 81 suicides *annually* (Niederkröthenthaler & Sonneck, 2007). *Finally, research suggests that not only does reporting on suicide in a negative way (e.g., reporting on suicide myths and repetition) have harmful effects on suicide, but reporting on positive coping skills in the face of adversity can also demonstrate protective effects against suicide* (Niederkröthenthaler et al., 2010). *Reports of individual suicidal ideation not accompanied by reports of suicide or suicide attempts, along with reports describing a "mastery" of a crisis situation where adversities were overcome, associated with significant decreases in suicide rates in the time period immediately following such reports* (Niederkröthenthaler et al., 2010).

**Comment [A]:** From TS: Don't you mean "Recommendations for Reporting on Suicide"?

Please cite:

<http://ajsp.org/wp-content/uploads/2016/01/recommendations.pdf>

The media did not want "guidelines" and they reacted negatively to the idea of external guidelines.

KH: Edited accordingly. I didn't realize they didn't like the idea of "guidelines" - interesting.

**Comment [A]:** I think this is a better link.

**Comment [A]:** From TS: Are you sure that the 81 reduction was just on the subway system? I thought that was nationally. Please confirm.

KH: it was nationally – apologies for the oversight in the way this was written.

**Comment [A]:** From TS: Thomas also had a 2010 report that suggested benefits of good reporting.

<http://bjp.rcpsych.org/content/bjprpsych/197/3/234.full.pdf>

KH: Added.

## Sector Involvement

Public health can play an important and unique role in addressing suicide. Public health agencies, which typically place prevention at the forefront of efforts and work to create broad population-level impact, can bring critical leadership and resources to bear on this problem. For example, these agencies can serve as a convener, bringing together partners and stakeholders to plan, prioritize, and coordinate suicide prevention efforts. Public health agencies are also well positioned to collect and disseminate data, implement preventive measures, evaluate programs, and track progress. Although public health can play a leadership role in preventing suicide, the strategies and approaches outlined in this technical package cannot be accomplished by the public health sector alone. As noted in the National Strategy to Prevent Suicide, the integration and coordination of prevention activities across sectors and settings is critical for expanding the reach and impact of suicide prevention efforts.

Other sectors vital to implementing this package include, but are not limited to, education, government (local, state, and federal), social services, health services, business, labor, justice, housing, media, and organizations that comprise the civil society sector such as faith-based organizations, youth-serving organizations, foundations, and other non-governmental organizations. Collectively, these sectors can make a difference in preventing suicide by impacting the various contexts and underlying risks that contribute to suicide.

The strategies and approaches described in this technical package are summarized in Appendix A along with the relevant sectors that are well positioned to lead implementation efforts. For example, business and labor, health care insurers and providers, and government entities are in the best position to implement programs and policies that *Strengthen Economic Supports and Access to Mental Health Care*. These types of supports go beyond individual behavior change and require commitment and support from those sectors that can directly address some of the underlying risks and the environmental contexts that increase the risk for suicide. Public health entities can play an important role by gathering and synthesizing information to inform policy, raise awareness, and evaluate the effectiveness of various policies. Moreover, partnerships with non-governmental and community organizations can be instrumental in increasing awareness of and garnering support for policies affecting individuals and families.

The public health sector has been at the forefront of many community-based prevention efforts, working collaboratively with schools and community-based organizations, to change social norms and positively impact health behavior. Public health is well suited to take on a similar leadership role in *Promoting*

*Connectedness* through peer norm and community engagement activities and supporting the development, evaluation, and adoption of effective programs that *Teach Coping and Problem-Solving Skills* to prevent suicide from happening in the first place. These programs are often delivered in school and community settings, making education and non-governmental organizations vital partners in prevention.

Businesses, workplaces, and local and state government entities, on the other hand, are in the best position to establish policies and support practices that *Create Protective Environments* where people live, work, and play. Public health entities can play an important role by gathering and synthesizing information, working with other agencies within the executive branch of their state or local government in support of policy and other approaches, and evaluating the effectiveness of measures taken. In a similar fashion, public health entities can partner with schools, workplaces, and community organizations to implement and evaluate prevention programs, policies and practices geared toward creating safe, healthy, and supportive environments.

Finally, this technical package includes a number of interventions delivered in hospital, primary care, behavioral health care, and community settings designed to *Identify and Support People At-Risk* and to *Lessen Harms and Prevent Future Risk*. The intensity and activities of these interventions require the expertise of professionals who are licensed and trained to deliver critical intervention support. The health care, social services, and justice sectors can work collaboratively to support individuals at high-risk for suicide and their families. These activities also require coordination of supports across various service providers and community organizations.

Regardless of strategy, action by many sectors will be necessary for the successful implementation of this package. In this regard, all sectors can play an important and influential role in preventing suicide from happening in the first place and lessening the immediate and long-term harms of suicidal behavior by helping those in times of crisis get the services and support they need.

## Monitoring and Evaluation

Monitoring and evaluation are necessary components of the public health approach to prevention. It is important to have timely and reliable data to monitor the extent of the problem and to evaluate the impact of prevention efforts. Data are necessary for program implementation as planning, implementation, and assessment all rely on accurate measurement of the problem.

Surveillance data helps researchers and practitioners track changes in the burden of suicide. Surveillance systems exist at the federal, state, and local levels. It is important to assess the availability of surveillance data and data systems across these levels to identify and address gaps in the systems. CDC's National Vital Statistics System and the National Violent Death Reporting System (NVDRS) are examples of surveillance systems that provide data on deaths from suicide. NVDRS, for example, is a state-based surveillance system that combines data from death certificates, law enforcement reports, and coroner or medical examiner reports to provide detailed information on the circumstances of violent deaths, including suicide, which can assist communities in guiding prevention approaches (Blair, Fowler, Jack, & Crosby, 2016). The National Electronic Injury Surveillance System-All Injury Program (NEISS-AIP) provides nationally representative data about all types and causes of nonfatal injuries treated in U.S. hospital emergency departments, and can be used to assess national rates of, and trends in, self-harm injuries by cause (e.g., falls, poisoning, etc.), age, race/ethnicity, sex, disposition (where the injured person goes when released from the Emergency Department).

In addition to information on deaths and nonfatal injuries, there are also surveillance systems that provide national, state, and some local estimates of suicidal behavior. The Youth Risk Behavior Surveillance System (YRBSS) collects information from a nationally representative sample of 9-12 grade students and is a key resource in monitoring health-risk behaviors among youth, including whether youth have seriously considered attempting suicide, attempted suicide, made a plan, or required treatment by a doctor or nurse for a suicide attempt that resulted in an injury, poisoning, or overdose (Brener et al., 2013). The YRBSS data are obtained from a national school-based survey conducted by CDC as well as from state, territorial, tribal, and large urban school district surveys conducted by education and health agencies. The National Survey on Drug Use and Health (NSDUH) is an annual survey of the civilian, non-institutionalized population aged 12 years and older. NSDUH provides both national and state-level estimates of substance use, including alcohol, tobacco, illicit drugs, and non-medical use of prescription drugs; and mental health, including past year mental illness, co-occurring illnesses, service utilization, along with suicide ideation, suicide plans, and suicide attempts. NSDUH is a key resource to track trends in suicide-related risk factors in the population and to help identify groups at increased risk.

It is also important at all levels (local, state, and federal) to address gaps in responses, track progress of prevention efforts and evaluate the impact of those efforts, including the impact of this technical package. Evaluation data, produced through program implementation and monitoring, is essential to provide information on what does and does not work to reduce rates of suicide and its associated risk

**Comment [A]:** From TS: This description seems incomplete compared to the description of YRBS

and protective factors. Theories of change and logic models that identify short, intermediate, and long-term outcomes are an important part of program evaluation.

The evidence-base for suicide prevention has advanced greatly over the last few decades. However, additional research is needed to understand the impact of programs, policies, and practices on suicide (and suicide attempts, at a minimum), as opposed to merely examining their effectiveness on risk factors associated with suicide. More research is also needed to examine the effectiveness of upstream (before risk occurs) and community-level strategies to prevent suicide at the population level. Lastly, it will be important for researchers to test the effectiveness of combinations of the strategies and approaches included in this package. Most existing evaluations focus on approaches implemented in isolation, but there is potential to understand the synergistic effects within a comprehensive prevention approach. ~~Additional research is needed to understand the extent to which combinations of strategies and approaches result in greater reductions in suicide than individual programs, practices, or policies.~~

## Conclusion

Suicide is a serious public health problem whose rates have been on the rise for more than a decade and whose costs stretch well into the billions of dollars each year. While suicide is a rare outcome statistically, its human impact has a ripple effect that is far-reaching. Each of us likely interacts with suicide survivors, those with lived experience, and those with thoughts of suicide, on a daily basis--at home, at work, and in our communities. Suicide and suicide attempts are therefore public health issues of societal concern. Fortunately, like many public health problems, suicide is preventable, and fortunately more is being done to prevent suicide than ever before, as evidenced by the work of the National Action Alliance for Suicide Prevention, the release of the first world report on suicide, and more timely surveillance data, to name just a few examples. Unfortunately and unlike most other public health problems, suicide prevention must still overcome struggles against the stigma, shame, and secrecy related to help-seeking, mental illness, being a survivor, or someone with lived experience; misplaced fear of-related to asking someone about their risk of suicide (versus the fear and consequence of *not* asking), and fear of taking up strategies known to be effective but perhaps unpopular; misinformation about suicide preventability, misplaced emphasis by the media and others on sensational aspects of suicide, and disproportionate funding given its public health burden. ~~Suicide also struggles against the right degree of awareness where too much information, for example by well-meaning reporters and others, may actually do harm.~~

In an effort to continue pushing the field and society further towards prevention, this technical package includes strategies and approaches that ideally would be used in a comprehensive fashion, in combination--in a multi-level, multi-sectoral way. This technical package includes strategies and approaches targeting (upstream prevention) (e.g., social emotional learning for children and youth), as well as strategies focused more downstream (e.g., cognitive behavioral treatment to prevent re-

**Comment [A]:** From TS: Should this be programs, policies, and practices to be consistent?

**Comment [A]:** From JH: including attempts?

**Comment [A]:** From JH: redundant with prior sentence.

**Comment [A]:** From TS: I found this somewhat awkward. The idea of suicide struggling seemed off and the point is not entirely clear. I think you can be more specific and reference an earlier point in the media recommendations section.

**Comment [A]:** From JH: Upstream/downstream is jargon.

**Comment [A]:** I prefer to keep this language in if it's ok. The e.g. is meant to help define the terms and it's been mentioned previously and defined. It's also a continued topic of discussion in the field that we need to focus more upstream. Iterating and re-iterating it is good I think. And lastly, there's a lot of jargon and terms in here that we'd also have to get rid of if we're honest about the use of jargon and reading level!

attempts). It includes ~~(universal, selective, and indicated strategies, or)~~ strategies that range from a focus on the whole population regardless of risk to strategies designed to support people at highest risk. Importantly, this technical package extends the bounds of the typical prevention strategies to consider approaches ~~at the (outer levels of the social ecology)~~ that go beyond individual behavior change to better address risk factors impacting communities and populations more broadly e.g., policies to stabilize housing and community engagement initiatives.

While the evidence base continues to emerge, the collection of programs, policies, and practices laid out here are available for implementation now. And in keeping with good public health practice, the intent is that monitoring and evaluation will play a key role in that implementation. Moreover, as new evidence becomes available, this technical package can be refined to reflect the current state of the science.

In closing, and in keeping with a message of resilience as spoken by those with lived experience, 'hope, help, and healing is possible.'

**Comment [A]:** From TS: I think you can drop this and just use the more descriptive text. You don't need both. You could describe this as a range.

**Comment [A]:** From JM: Yes this is jargon, so the e.g., helps, but you might want to figure out a way to say this without referring to the outer levels of the social ecology.

**Comment [A]:** This sets you up for people to say oh yeah what about... AI/AN, transgendered people, prisoners etc.

**Comment [A]:** I'm not exactly clear on how to take this comment and subsequently how to address it. Open to ideas.

## Appendix A: Summary of Strategies and Approaches to Prevent Suicide

Strategy	Approach/Program, Practice or Policy	Best Available Evidence			Lead Sectors <sup>1</sup>
		Suicide	Suicide Attempts or Ideation	Other Risk/Protective Factors for Suicide	
Strengthen economic supports	<b>Strengthen household financial security</b>				Government (local, state, Federal)
	<i>Unemployment benefit programs</i>	✓			
	<i>Other income supports</i>	✓			Business/labor
	<b>Housing stabilization policies</b>				Government (local, state, Federal)
	<i>The National Neighborhood Stabilization Program</i>			✓	
Strengthen access to mental health care	<b>Coverage of mental health conditions in health insurance policies</b>				Health care
	<i>Mental Health Parity Laws</i>	✓		✓	Government (state, Federal)
Establish protective environments	<b>Reducing access to lethal means among persons at-risk</b>				Government (local, state)
	<i>Intervening at suicide hot spots</i>	✓			
	<i>Safe storage practices</i>		✓	✓	Public Health
	<b>Organizational policies and culture</b>				Business/Labor
	<i>Together for Life</i>	✓			
	<i>US Air Force Suicide Prevention Program</i>	✓		✓	Government (local, state, Federal)

		Best Available Evidence			
	<b>Community-based policies to reduce excessive alcohol use</b>				Government (local, state)
	<i>Alcohol outlet density</i>	✓		✓	Business/labor
<b>Promote connectedness</b>	<b>Peer norm approaches</b>				Public Health
	<i>Sources of Strength</i>			✓	Education
	<b>Community-engagement activities</b>				Public Health
	<i>Greening vacant urban spaces</i>			✓	Government (local)
<b>Teach coping and problem-solving skills</b>	<b>Social emotional learning</b>				Public Health
	<i>Youth Aware of Mental Health Program</i>		✓		Education
	<i>Signs of Suicide</i>		✓	✓	
	<i>Good Behavior Game</i>		✓	✓	
	<b>Parenting skill and family relationship approaches</b>				Public Health
	<i>The Incredible Years</i>			✓	Education
	<i>Strengthening Families 10-14</i>			✓	
<b>Identify and</b>	<b>Gatekeeper training</b>				Public Health
	<i>Mental Health First Aid</i>			✓	Healthcare
	<b>Screening combined with care management</b>				Healthcare

		Best Available Evidence			
support people at-risk	<i>Henry Ford Perfect Depression Care (Pre-cursor to Zero Suicide)</i>	✓		✓	Social Services
	<b>Crisis Intervention</b>				Public Health
	<i>National Suicide Prevention Lifeline</i>		✓	✓	Social Services
	<i>Applied Suicide Intervention Skills Training</i>		✓	✓	
Intervene to lessen harms and prevent future risk	<b>Treatment for people at risk of suicide</b>				Healthcare
	<i>Improving Mood – Promoting Access to Collaborative Treatment (IMPACT)</i>		✓	✓	Social Services Justice
	<i>Collaborative Assessment and Management of Suicidality (CAMS)</i>		✓	✓	
	<i>Dialectical Behavioral Therapy</i>		✓	✓	
	<i>Attachment-Based Family Therapy</i>		✓		
	<b>Treatment to prevent re-attempts</b>				Healthcare
	<i>ED Brief Intervention with Follow-up Visits</i>	✓			Social Services
	<i>Active follow-up contact approaches</i>	✓	✓		
	<i>CBT for Suicide Prevention</i>				
	<b>Postvention</b>				Healthcare

		Best Available Evidence			
	<i>StandBy Response Service</i>		✓		
	<b>Safe messaging following a suicide</b>				Public Health
	<i>Media Guidelines</i>	✓			Media

<sup>1</sup>This column refers to the lead sectors well positioned to bring leadership and resources to implementation efforts. For each strategy, there are many other sectors such as non-governmental organizations that are instrumental to prevention planning and implementing the specific programmatic activities.

## Overview

This technical package represents a select group of strategies based on the best available evidence to help communities and states sharpen their focus on prevention activities with the greatest potential to prevent suicide. These strategies include strengthening economic supports; strengthening access to mental health care; creating protective environments; promoting connectedness; teaching coping and problem-solving skills; identifying and supporting people at-risk; and intervening to lessen harms and prevent future risk. The strategies represented in this package include those with a focus on preventing suicide from happening in the first place as well as approaches to lessen the immediate and long-term harms of suicidal behavior for individuals, families, communities, and society. The strategies in the technical package support the goals and objectives of the National Strategy for Suicide Prevention and the National Action Alliance for Suicide Prevention's priority to strengthen community-based prevention. Commitment, cooperation, and leadership from numerous sectors, including public health, education, justice, health care, social services, business, labor, and government can bring about the successful implementation of this package.

### What is a Technical Package?

A technical package is a compilation of a core set of strategies to achieve and sustain substantial reductions in a specific risk factor or outcome (Frieden, 2014). Technical packages help communities and states prioritize prevention activities based on the best available evidence. This technical package has three components. The first component is the **strategy** or the preventive direction or actions to achieve the goal of preventing suicide. The second component is the **approach**. The approach includes the specific ways to advance the strategy. This can be accomplished through *programs, policies, and practices*. The approaches included come primarily from studies based in the United States. The **evidence** for each of the approaches in preventing suicide or its associated risk factors is included as the third component. This package is intended as a resource to guide and inform prevention decision-making in communities and states.

### Preventing Suicide is a Priority

Suicide, as defined by the Centers for Disease Control and Prevention (CDC), is part of a broader class of behavior called *self-directed violence*. Self-directed violence refers to behavior directed at oneself that deliberately results in injury or the *potential* for injury (A.E. Crosby, Ortega, & Melanson, 2011). Self-directed violence may be *suicidal* or *non-suicidal* in nature. For the purposes of this document, we refer only to behavior where suicide is intended:

- **Suicide** is a death caused by self-directed injurious behavior with any intent to die as a result of the behavior.

- **Suicide attempt** is defined as a *non-fatal* self-directed and potentially injurious behavior with any intent to die as a result of the behavior. A suicide attempt may or may not result in injury.

**Suicide is highly prevalent.** Suicide presents a major challenge to public health in the United States and worldwide. It contributes to premature death, morbidity, lost productivity, and health care costs (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014). In 2014 (the most recent year of available death data), suicide was responsible for 42,773 deaths in the U.S., which is approximately one suicide every 12 minutes (Centers for Disease Control and Prevention, 2016d). In 2014, suicide ranked as the 10th leading cause of death and has been among the top 12 leading causes of death since 1975 in the U.S (Centers for Disease Control and Prevention, 2016d). Overall suicide rates have increased 24% from 1999 to 2014 (Curtin, Warner, & Hedegaard, 2016). Suicide is a problem throughout the life span; it is the second leading cause of death among those aged 10–34 years; it is the fourth leading cause among persons in their 40s and seventh among persons in their 50s. Suicide rates vary by race/ethnicity with the highest rates, across the lifespan, occurring among non-Hispanic American Indian/Alaska Native (AI/AN) (rate: 17.8/100,000). Among AI/AN, young people are disproportionately at increased risk of suicide with young males aged 25-29 experiencing the highest rates (rate: 56.9/100,000) (Centers for Disease Control and Prevention, 2016d). Moreover, suicide rates among non-Hispanic AI/AN have increased by 48.7% since 1999.

Suicides reflect only a portion of the problem (A.E. Crosby, Han, Ortega, Parks, & Gfroerer, 2011). Substantially more people are hospitalized as a result of nonfatal suicidal behavior (i.e. suicide attempts) than are fatally injured, and an even greater number are either treated in ambulatory settings (e.g., emergency departments) or not treated at all (A.E. Crosby, Han, et al., 2011). For example, during 2014, among adults aged 18 years and older, for every one suicide there were 9 adults treated in hospital emergency departments for self-harm injuries, 27 who reported making a suicide attempt, and over 227 who reported seriously considering suicide (i.e. ideation) (Ferdon et al., In press).

**Suicide is associated with several risk and protective factors.** Suicide, like other human behaviors, has no single determining cause. Instead, suicide occurs in response to multiple biological, psychological, interpersonal, environmental and societal influences that interact with one another, often over time. The social-ecological model-- encompassing multiple levels of focus from the individual, relationship, community, and societal-- is a useful framework for viewing and understanding suicide risk factors identified in the literature (Dahlberg & Krug, 2002). Risk and protective factors for suicide exist at each level. For example, risk factors include:

- **Individual level:** History of depression and other mental illnesses, hopelessness, substance abuse, certain health conditions, previous suicide attempt, violence victimization and perpetration, and genetic and biological determinants
- **Relationship level:** High conflict or violent relationships, sense of isolation and lack of social support, family/loved one's history of suicide, financial and work stress

- **Community level:** Inadequate community connectedness, barriers to health care (e.g., lack of access to providers and medications)
- **Societal level:** Availability of lethal means of suicide, unsafe media portrayals of suicide, stigma associated with help-seeking and mental illness (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014).

It is important to recognize that the vast majority of individuals who are depressed or who have other risk factors noted, do *not* die by suicide. Furthermore, the relevance of each risk factor can vary by age, race, gender, sexual orientation, residential geography, and socio-cultural and economic status (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014).

Protective factors, or those influences that guard *against* the risk for suicide, can also be found across the different levels of the social-ecological model. Protective factors identified in the literature include: effective coping and problem solving skills, moral objections to suicide, strong and supportive relationships with partners, friends, and family; connectedness to school, community and other social institutions; availability of quality and ongoing physical and mental health care, and reduced access to lethal means (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014). These protective factors can either counter a specific risk factor or guard against a number of risks associated with suicide.

**Suicide is connected to other forms of violence.** Suicide and other forms of violence often share some of the same root causes (Butchart, Phinney, Check, & Villaveces, 2004; Klevens, Simon, & Chen, 2012). For example, in neighborhoods where there is low social cohesion, or where residents don't support and trust each other, people are at higher risk for suicide (Desai, Dausey, & Rosenheck, 2005) as well as perpetration of child maltreatment (Coulton, Crampton, Irwin, Spilsbury, & Korbin, 2007; Freisthler, Merritt, & LaScala, 2006), teen dating violence (Capaldi, Knoble, Shortt, & Kim, 2012), intimate partner violence (Pinchevsky & Wright, 2012), and youth violence (Sampson, Morenoff, & Gannon-Rowley, 2002). Additionally, a lack of economic opportunities and unemployment are associated with suicide (Luo, Florence, Quispe-Agnoli, Ouyang, & Crosby, 2011; Reeves et al., 2012), as well as perpetration of child maltreatment (D. Runyan, Wattam, Ikeda, Hassan, & Ramiro, 2002), intimate partner violence (Heise & Garcia-Moreno, 2002; Pinchevsky & Wright, 2012), sexual violence (Centers for Disease Control and Prevention, 2016c) and youth violence (Wilson, 2011). Other shared risk factors for suicide and violence occur at the individual level and include substance abuse, mental health problems, witnessing violence, and a lack of problem-solving skills (Centers for Disease Control and Prevention, 2016a, 2016c, 2016e; U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012).

Just as risk factors may be shared across suicide and violence, so too may protective factors overlap. For example, ~~connectedness increases individual's and communities' resilience to suicide and other forms~~

~~of violence, including~~ connectedness to one's community (Basile, Hamburger, Swahn, & Choi, 2013; Borowsky, Hogan, & Ireland, 1997; Centers for Disease Control and Prevention, 2016b; Coulton et al., 2007; Kleiman, Riskind, Schaefer, & Weingarden, 2012; Pinchevsky & Wright, 2012; Widome, Sieving, Harpin, & Hearst, 2008), school (Basile, Espelage, Rivers, McMahon, & Simon, 2009; Capaldi et al., 2012; Carter, McGee, Taylor, & Williams, 2007; DeGue et al., 2013; Hong, Kral, Espelage, & Allen-Meares, 2012; Losel & Farrington, 2012), family (Capaldi et al., 2012; Centers for Disease Control and Prevention, 2016a; Elgar, Craig, Boyce, Morgan, & Vella-Zarb, 2009; Maimon, Browning, & Brooks-Gunn, 2010; Resnick, Ireland, & Borowsky, 2004), caring adults (Capaldi et al., 2012; Losel & Farrington, 2012; Maimon et al., 2010), and pro-social peers (Capaldi et al., 2012; Losel & Farrington, 2012) enhances resilience to suicide and other forms of violence.

**The health and economic consequences of suicide are substantial.** Suicide and suicide attempts have far-reaching consequences for individuals, families, and communities (Dunne, McIntosh, & Dunne-Maxim, 1987; Mishara, 1995; National Action Alliance for Suicide Prevention: Suicide Attempt Survivors Task Force, 2014; National Action Alliance for Suicide Prevention: Survivors of Suicide Loss Task Force, 2015). In an early study, Crosby and Sacks (2002) estimated that 7% of the U.S. adult population, or 13.2 million adults, knew someone in the prior 12 months who had died by suicide. They also estimated that for each suicide, 425 adults were exposed, or knew about the death. In a more recent study, in one state, Cerel et al. (2016) found that 48% of the weighted survey population knew at least one person who died by suicide in their lifetimes. Research indicates that the impact of knowing someone who died by suicide and/or having lived experience (i.e. having attempted suicide oneself) is much more extensive than injury and death. Suicide attempt survivors may suffer long-term health and mental health consequences ranging from anger, guilt, and physical impairment, depending on the means and severity of the attempt (Chapman & Dixon-Gordon, 2007). Similarly, survivors of a loved one's suicide may experience ongoing pain and suffering including complicated grief (Mitchell, Kim, Prigerson, & Mortimer-Stephens, 2004), stigma, depression, anxiety, post-traumatic stress disorder, and increased risk of suicidal ideation and suicide (Julie Cerel, McIntosh, Neimeyer, Maple, & Marshall, 2014; Sudak, Maxim, & Carpenter, 2008). In addition to the emotional and physical toll, survivors of suicide may also struggle financially and occupationally (Florence, Simon, Haegerich, Luo, & Zhou, 2015).

The economic toll of suicide is immense as well. According to more conservative estimates, in 2013, suicide cost \$50.8 billion in estimated lifetime medical and work-loss costs (Florence et al., 2015). By another estimate, the total lifetime costs associated with nonfatal injuries and deaths caused by self-directed violence in 2013 were approximately \$93.5 billion after adjusting for under-reporting of suicide (Shepard, Gurewich, Lwin, Reed, & Silverman, 2016). The overwhelming burden of these costs results from lost productivity over the life course, with the average cost per suicide being over \$1.3 million (Shepard et al., 2016).

**Comment [A]:** From TS: I found this wording somewhat awkward.

**Comment [A]:** From TS: It seems like it would be appropriate to acknowledge the CDC estimate too. Consider using that as a minimum and then say that others have estimated that the costs could be considerably higher after adjusting for under-reporting of suicide.

**Suicide can be prevented.** Despite the myths surrounding suicide, like most public health problems, suicide is preventable (U.S. Public Health Service, 1999). And while progress will continue to be made into the future, evidence for numerous programs, practices, and policies currently exists, and many programs are ready to be implemented now. Just as suicide is not caused by a single factor, research suggests that suicide will not be prevented by any single intervention taking place in any single setting (Silverman & Maris, 1995; U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012). Rather, suicide prevention is best achieved by a focus across the individual, relationship, family, community, and societal-levels and across all sectors, private and public (e.g., business, public health, physical and behavioral healthcare, justice, education, labor) (National Action Alliance for Suicide Prevention, 2014; World Health Organization, 2014).

### Assessing the Evidence

This technical package includes programs, practices, and policies with evidence of impact on suicide or risk or protective factors for suicide. To be considered for inclusion in the technical package, the program, practice, or policy selected had to meet at least one of these criteria: a) meta-analyses or systematic reviews showing impact on suicide; b) evidence from at least one rigorous (e.g., randomized controlled trial [RCT] or quasi-experimental design) evaluation study that found significant preventive effects on suicide; c) meta-analyses or systematic reviews showing impact on risk or protective factors for suicide, or d) evidence from at least one rigorous (e.g., RCT or quasi-experimental design) evaluation study that found significant impacts on risk or protective factors for suicide. Finally, consideration was also given to the likelihood of achieving beneficial effects on multiple forms of violence; no evidence of harmful effects on specific outcomes or with particular subgroups; and feasibility of implementation in a U.S. context if the program, policy, or practice has been evaluated in another country.

Within this technical package, some approaches do not yet have research evidence demonstrating impact on rates of suicide but instead are supported by evidence indicating impacts on risk or protective factors for suicide (e.g., help-seeking, stigma reduction, depression, connectedness). In terms of the strength of the evidence, programs that have demonstrated effects on suicidal behavior (e.g., reductions in deaths, attempts) provide a higher-level of evidence, but the evidence base is not that strong in all areas. For instance, there has been less evaluation of community engagement and family programs on suicidal behavior. Thus, approaches in this package that have effects on risk or protective factors reflect the **(developing mental)** nature of the evidence base and the use of the best available evidence at a given time.

It is also important to note that there is often significant heterogeneity among the programs, policies, or practices that fall within one approach or strategy area in terms of the nature and quality of the available evidence. Not all programs, policies, or practices that utilize the same approach (e.g., gatekeeper training) are equally effective, and even those that are effective may not work across all populations. Tailoring programs and more evaluation may be necessary to address different population groups. The

**Comment [A]:** From TS: “developmental nature” doesn’t seem correct. Do you mean the “current status”

examples provided are not intended to be a comprehensive list of evidence-based programs, policies, or practices for each approach, but rather illustrate models that have been shown to impact suicide or have beneficial effects on risk or protective factors for suicide. In practice, the effectiveness of the programs, policies and practices identified in this package will be strongly dependent on the quality of their implementation and the communities in which they are implemented. Implementation guidance to assist practitioners, organizations and communities will be developed separately.

### Context and Cross-Cutting Themes

The strategies and approaches that have been included in this technical package represent different levels of the social ecology, with efforts intended to impact the community and societal levels, as well individual and relationship levels. The strategies and approaches are intended to work in combination and reinforce each other to prevent suicide (see box below). The strategies are arranged in order such that those strategies hypothesized to have the greatest potential for broad public health impact on suicide are included first, followed by those that might impact more select populations (e.g., persons who have already made a suicide attempt).

Preventing Suicide	
Strategy	Approach
Strengthen economic supports	<ul style="list-style-type: none"> <li>Strengthen household financial security</li> <li>Housing stabilization policies</li> </ul>
Strengthen access to mental health care	<ul style="list-style-type: none"> <li>Coverage of mental health conditions in health insurance policies</li> </ul>
Create protective environments	<ul style="list-style-type: none"> <li>Reducing access to lethal means among persons at-risk of suicide</li> <li>Organizational policies and culture</li> <li>Community-based policies to reduce excessive alcohol use</li> </ul>
Promote connectedness	<ul style="list-style-type: none"> <li>Peer norm approaches</li> <li>Community engagement activities</li> </ul>
Teach coping and problem-solving skills	<ul style="list-style-type: none"> <li>Social-emotional learning</li> <li>Parenting skill and family relationship approaches</li> </ul>
Identify and support people at risk	<ul style="list-style-type: none"> <li>Gatekeeper training</li> <li>Screening combined with care management</li> <li>Crisis intervention</li> </ul>
Intervene to lessen harms and prevent future risk	<ul style="list-style-type: none"> <li>Treatment for people at-risk of suicide</li> <li>Treatment to prevent re-attempts</li> <li>Postvention</li> </ul>

The example programs, policies, and practices have been implemented within particular contexts. The social and cultural context of communities is critically important to take into account when selecting strategies and approaches. Practitioners in the field may be in the best position to assess the needs and strengths of their communities and work with community members to make decisions about the combination of approaches included here that are best suited to their context.

Suicide ideation, attempts, morbidity and mortality vary by gender, race/ethnicity, age, occupation, and other important population characteristics. Barriers to disclosure, help seeking, timely access to quality care, and ongoing support may also vary by population and community characteristics. Ideally, the availability of multiple approaches tailored to the economic, cultural, and environmental context of individuals and communities are desirable as they may increase the likelihood of removing barriers to supportive and effective care and provide opportunities to develop individual and community resilience. These culturally appropriate approaches can then be included in comprehensive strategies to maximize the public health impact on reducing suicide-related morbidity and mortality among individuals and within communities.

This package includes strategies where public health agencies are well positioned to bring leadership and resources to implementation efforts. It also includes strategies where public health can serve as an important collaborator (e.g., strategies addressing community and societal level risks), but where leadership and commitment from other sectors such as business, labor or health care is critical to implement a particular policy or program (e.g., workplace policies; screening combined with care management). The role of various sectors in the implementation of a strategy or approach in preventing suicide is described further in the section on *Sector Involvement*.

In the sections that follow, the strategies and approaches with the best available evidence for preventing suicide are described.

## Strengthen Economic Supports

### Rationale

Studies from the U.S. examining historical trends indicate that suicide rates increase during economic recessions marked by high unemployment rates, job losses, and economic instability and decrease during economic expansions and periods marked by low unemployment rates, particularly for working-age individuals 25 to 64 years old (Luo et al., 2011; Fowler et al., 2015). Economic and financial strain, such as job loss, long periods of unemployment, reduced income, difficulty covering medical, food, and housing expenses, and even the anticipation of such financial stress, can directly or indirectly increase an individual's risk for suicide; buffering these risks can therefore, potentially protect against suicide (Stack & Wasserman, 2007). For example, strengthening economic support systems can help people stay in their homes or obtain affordable housing while also paying for necessities such as food and medical care, job training, child care, among other expenses required for daily living. In providing this support, stress and anxiety and the potential for a crisis situation may be reduced, thereby preventing suicide.

### Approaches

Economic supports for individuals and families can be strengthened by targeting household financial security and ensuring stability in housing during periods of economic stress.

- **Strengthening household financial security** can potentially buffer the risk of suicide by providing individuals with the financial means to lessen the stress and hardship associated with a job loss or other unanticipated financial problems. The provision of unemployment benefits and other forms of temporary assistance, livable wages, medical benefits, and retirement and disability insurance to help cover the cost of necessities or to offset costs in the event of disability, are examples of ways to strengthen household financial security.
- **Housing stabilization policies** aim to keep people in their homes and provide housing options for those in need during times of financial insecurity. This may occur through programs that provide affordable housing such as through government subsidies or through other options available to potential homebuyers such as loan modification programs, move-out planning, or financial counseling services that help minimize the risk or impact of foreclosures and eviction.

### Potential Outcomes

- Reduced suicide rates
- Lower foreclosure rates
- Lower eviction rates
- Reduced emotional distress

**Comment [A]:** From TS: I was thinking that it might be good to work in a point about how these risks can be directly or indirectly associated with suicide risk because these stressors can exacerbate relationship as well physical and mental health problems.

**Comment [A]:** From JH: Consistent tense – reduced vs. reduce

**Comment [A]:** From LLD: the other packages use "Reductions in..."; you may want to consider using similar language for your potential outcomes.

## Evidence

There is evidence suggesting that strengthening household financial security and stabilizing housing can reduce suicide risk.

- **Strengthen household financial security.** An examination of variations in U.S. *unemployment benefit programs* across states demonstrated that the impact of unemployment on suicide was offset in those states that provided greater than average unemployment benefits (Cylus, Glymour, & Avendano, 2014). Another U.S. study examining the link between unemployment and suicide risk using monthly suicide data, length of unemployment, and job losses found that the duration of unemployment, as opposed to just the loss of job, predicted suicide risk (Classen & Dunn, 2012). Together, these results suggest that not only should state unemployment benefit programs be generous in their financial allocations, but also in their duration.

Other measures to strengthen household financial security (e.g., transfer payments related to retirement and disability insurance, unemployment insurance compensation, medical benefits, and other forms of family assistance) have also shown an impact on suicide. A study by Flavin and Radcliff (2009) examined the impact of states' per capita spending on transfer payments, medical benefits, and family assistance (Temporary Assistance to Needy Families – TANF) and total state spending on suicide rates between 1990-2000, controlling for a number of suicide risk factors (e.g., residential mobility, divorce rate, unemployment rate) at the state level. As per capita spending on total transfer payments, medical benefits, and family assistance increased there was an associated decrease in state suicide rates. Moreover, it wasn't spending in general that was associated with the reduction but spending on these types of assistance. In terms of lives saved, Flavin & Radcliff calculated the cost of reducing a state's suicide rate by a full point for the years studied. At the national level, they estimated that 3,000 fewer suicides would occur per year nationwide if every state increased their per capita spending on these types of assistance by \$45 per year (Flavin & Radcliff, 2009).

- **Housing stabilization policies.** The *National Neighborhood Stabilization Program* was designed to help neighborhoods suffering from high rates of foreclosure and abandonment by slowing the deterioration of the neighborhoods and providing affordable housing options for low, moderate, and middle-income homebuyers. This program also offers financial assistance to eligible individuals for the purchase of a new home. Although this program has not been rigorously evaluated for its impact on suicide outcomes, it addresses foreclosure and eviction, which are risk factors for suicide. A longitudinal analysis of annual data on suicides and foreclosures demonstrated that as the proportion of foreclosed properties increased in U.S. states, so did the state suicide rate, particularly among working-aged adults (Houle & Light, 2014). Another study

**Comment [A]:** From TS: Consider including a point about this being a correlational study and more evaluation work is needed but it suggests the potential benefits of policies that reach those who are particularly vulnerable at the times when they are in greatest need.

of data from 16 U.S. states participating in the National Violent Death Reporting System found that suicides precipitated by home foreclosures and evictions increased more than 100% from 2005 (before the housing crisis began) to 2010 (after it had peaked; Fowler, Gladden, Vagi, Barnes, and Frazier (2015)). Most of these suicides occurred prior to the actual loss of the decedent's home. These findings suggest that integrating suicide prevention resources, messaging, and referrals into financial, foreclosure, and move-out planning and counseling services may help to prevent suicide.

## Strengthen Access to Mental Health Care

### Rationale

While most people with mental health problems do not attempt or die by suicide (Olfson, Gerhard, Huang, Crystal, & Stroup, 2015; Owens, 2002), and risk conferred by mental illnesses differ (Arsenault-Lapierre, Kim, & Turecki, 2004; E. C. Harris & Barraclough, 1997; Tyrer, Reed, & Crawford, 2015), previous research indicates that mental illness is an important risk factor for suicide (E. C. Harris & Barraclough, 1998; World Health Organization, 2014). Studies suggest that up to 90% of people who die by suicide may have had a mental illness at the time of their deaths (Arsenault-Lapierre et al., 2004; Cavanagh, Carson, Sharpe, & Lawrie, 2003; Isometsa, 2001). State-level suicide rates have also been found to be correlated with general mental health measures such as depression (Lang, 2013; Mark, Shern, Bagalman, & Cao, 2007). Findings from the National Comorbidity Survey indicate that relatively few people in the U.S. with mental health disorders receive treatment for those conditions (Kessler et al., 2005). Lack of access to mental health care is one of the contributing factors related to the underuse of mental health services (Cunningham, 2009). Identifying ways to improve access to timely, affordable, and quality mental health care for people in need is a critical component to suicide prevention (World Health Organization, 2014). Apart from the treatment benefits, it can also serve to normalize help-seeking behavior and increase the use of such services.

### Approaches

One approach to strengthening access to mental health care is through the provision of mental health coverage in health insurance policies.

- **Coverage of mental health conditions in health insurance policies.** Federal and state laws include provisions for equal coverage of mental health services in health insurance plans that is on par with coverage for other health concerns (i.e., mental health parity). Benefits and services covered include such things as the number of visits, co-pays, deductibles, inpatient/outpatient services, prescription drugs, and hospitalizations. If a state has a stronger mental health parity law than the federal parity law, then insurance plans regulated by the state must follow the state parity law. Federal parity replaces the state law only in cases where the state law prevents the application of the federal parity law (e.g., includes coverage for some mental health conditions but not others). Equal coverage does not necessarily imply good coverage as health insurance plans vary in the extent to which benefits and services are offered to address various health conditions. Rather it helps to ensure that mental health services are covered on par with other health concerns.

### Potential Outcomes

- Increased utilization of mental health services

**Comment [A]:** From JM: I assume this means that different types of mental health problems pose different risks for suicide, but wasn't sure? May want to make the point more explicit

**Comment [A]:** From TS: Isn't this including substance abuse disorder? It would be good to state this explicitly.

**Comment [A]:** From TS: I found this sentence confusing. Can you reword to simplify this.

From LLD: could say: "if a state has a weaker parity law than the federal parity law (e.g., includes coverage for some mental health conditions but not others), then the federal parity law will replace the state law."

- Decreased symptoms of mental illnesses
- Decreased rates of suicide attempts
- Decreased rates of suicide

### Evidence

There is evidence suggesting that coverage of mental health conditions in health insurance policies can reduce risk factors associated with suicide and may directly impact suicide rates.

- **Coverage of mental health conditions in health insurance policies.** The National Survey of Drug Use and Health is a nationally representative survey of the U.S. population that provides data on substance use, mental health conditions, and services utilization. Using data from this survey, K. M. Harris, Carpenter, and Bao (2006) found that 12 months after states enacted *mental health parity laws*, self-reported use of mental healthcare services significantly increased. Moreover, subsequent research by Lang (2013) examined state mental health laws and suicide rates between 1990 and 2004 and found that mental health parity laws, specifically, were associated with an approximate 5% reduction in suicide rates. This reduction, in the 29 states with parity laws, equated to the prevention of 592 suicides per year. Lang et. al (2013) estimated the cost of saving a life through such mandates as mental health parity by comparing the loss in wages attributable to the policy, via increased premiums, to the number of lives saved. Based on these calculations, the cost of saving one life was between and a cost savings of \$1.3-3.1 million. However, this calculation did not take into account the saving associated with improved mental health among non-suicidal individuals, increases in productivity, or quality of life associated with increased mental health care. As such, this figure is considered the upper bounds on costs incurred and should be interpreted with caution per suicide prevented (Lang, 2013).

**Comment [A]:** From TS: I don't think this is accurate. I was curious about this study and checked out the paper. I think they are saying that this is the cost incurred per suicide prevented. They go on to explain that this is the upper bound and does not reflect the benefits to non-suicidal individuals. Please confirm this. If you are going to include this then it will be important to explain it further.

## Create Protective Environments

### Rationale

Prevention efforts that focus not only on individual behavior change (e.g., help-seeking, treatment interventions) but on changes to the environment can increase the likelihood of positive behavioral and health outcomes (Haddon, 1980). Creating environments that address risk and protective factors where individuals live, work, and play, can help prevent suicide (Dahlberg & Krug, 2002; U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012). For example, rates of suicide and suicide attempts are elevated in certain occupational groups (Han et al., 2016; McIntosh et al., 2016), therefore, changes to the organizational culture in these occupations, by way of implementation of supportive policies or even physical modifications to the workplace environment, can change social norms, encourage help-seeking, and demonstrate that good health and mental health are valued and that stigma and other risk factors for suicide are not (K. L. Knox et al., 2010; National Action Alliance for Suicide Prevention Workplace Task Force, 2015). Similarly, modifying the characteristics of the environment to prevent harmful behavior such as access to lethal means can reduce suicide rates, particularly in times of crisis (Beautrais, Gibb, Fergusson, Horwood, & Larkin, 2009; A.E. Crosby, Espitia-Hardeman, Ortega, & Lozano, 2013; Kaplan et al., 2013; Miller, Warren, Hemenway, & Azrael, 2015; C. W. Runyan et al., 2016).

### Approaches

The current evidence suggests three **promising** approaches for creating environments that protect against suicide.

- **Reducing access to lethal means among persons at-risk of suicide.** Means of suicide such as firearms, hanging/suffocation, or jumping from heights provide little opportunity for rescue and, as such, have high case fatality rates (e.g., about 85% of people who use a firearm in a suicide attempt will die from the injury). Research also indicates that 1) the interval between thinking about and attempting suicide can be as short as 5 or 10 minutes (Deisenhammer et al., 2009; Simon et al., 2001) and 2) that people tend *not* to substitute a different method when a highly lethal method is unavailable or difficult to access (Hawton, 2007; Yip et al., 2012). Therefore, increasing the time interval between the thought and the suicide attempt, for example, by making it more difficult to access lethal means, can be lifesaving. The following are examples of approaches reducing access to lethal means for persons at-risk of suicide:
  - *Intervening at Suicide Hotspots.* Suicide hotspots, or places where suicides may take place relatively easily, include tall structures (e.g., bridges and cliffs), railway tracks, and isolated locations such as parks. Efforts to prevent suicide at these locations include

**Comment [A]:** From JM: The word promising has certain connotations when using it around evidence. You say later that the evidence around this strategy is some of the strongest for suicide. These two statements seem somewhat inconsistent. I would use a different word here then promising if you truly believe there is strong evidence.

From JH: suggest deleting the word "promising"

From LLD: since we don't want to infer that these are the only approaches for creating protective environments, I might be inclined to change the word "promising" to "potential" or "possible" or something along those lines.

erecting barriers to prevent jumping and installing signs and telephones to encourage individuals who are considering suicide, to seek help (Cox et al., 2013).

- *Safe Storage Practices.* Safe storage of medications, firearms, and other household products can reduce the risk for suicide by separating individuals who may be vulnerable and/or impulsive from easy access to lethal means. Such practices may include education and counseling around storing firearms--locked in a secure place (e.g., in a gun safe or lock box), unloaded and separate from the ammunition--and keeping medicines in a locked cabinet or other secure location away from people who may be at risk or who have made prior attempts (Rowhani-Rahbar, Simonetti, & Rivara, 2016; C. W. Runyan et al., 2016).

- **Organizational policies and culture** that promote protective environments may be implemented in places of employment. Such policies and cultural values may promote prosocial behavior (e.g., asking for help), skill building, changing social norms, referral and access to helping services (e.g. mental health, substance abuse treatment, financial counseling), and encourage leadership support from the top down. Such policies and cultural shifts can positively impact organizational climate and morale and help prevent suicide and its related risk factors (e.g. depression, social isolation) (National Action Alliance for Suicide Prevention Workplace Task Force, 2015).
- **Community-based policies to reduce excessive alcohol use.** Research studies in the United States have found that greater alcohol availability is positively associated with alcohol-involved suicides (Escobedo & Ortiz, 2002; Giesbrecht et al., 2015). Policies to reduce excessive alcohol use broadly include zoning to limit alcohol outlet locations and density, taxes on alcohol, and bans on the sale of alcohol for individuals under the legal drinking age. These policies are important because acute alcohol use has been found to be associated with more than one-third of suicides and approximately 40% of suicide attempts (Cherpitel, Borges, & Wilcox, 2004).

#### Potential Outcomes

- Increase in safe storage of means
- Reduction in suicide attempts
- Reduction in suicide deaths
- Increase in help-seeking
- Reduction in alcohol-related suicide deaths

#### Evidence

The evidence for the effectiveness reducing access to lethal means for person at-risk of suicide and other ways to establish protective environments is some of the strongest in the field (Zalsman et al., 2016).

**Comment [A]:** From JM: Consistent with promising used earlier? Is it the strongest?

- **Reducing access to lethal means among persons at-risk of suicide.** A meta-analysis examining the impact of *suicide hotspot interventions* implemented in combination or in isolation, both in the U.S. and abroad, found associated reduced rates of suicide (Cox et al., 2013; Pirkis et al., 2015). For example, after erecting a barrier on the Jacques-Cartier bridge in Canada, the suicide rate from jumping from the bridge decreased from about 10 suicide deaths per year to about 3 deaths per year (Perron, Burrows, Fournier, Perron, & Ouellet, 2013). Moreover, the reduction in suicides by jumping was sustained even when all bridges and nearby jumping sites were considered, suggesting little to no displacement of suicides to other jumping sites (Perron et al., 2013). Further evidence for the effectiveness of bridge barriers was demonstrated by a study examining the impact of the *removal* of safety barriers from the Grafton Bridge in Auckland, New Zealand. After removal of the barrier, both the number and rate of suicide increased fivefold (Beautrais, 2001; Beautrais et al., 2009).

Another form of means reduction involves implementation of *safe storage practices*. In a case-control study of firearm-related events identified from 37 counties in Washington, Oregon, and Missouri, and from 5 trauma centers, Grossman et al. (2005) found that storing firearms unloaded, separate from ammunition, in a locked place or secured with a safety device was protective of suicide attempts among adolescents. Further, a recent systematic review of clinic and community-based education and counseling interventions suggested that the provision of safety devices significantly increased safe firearm storage practices compared to counseling alone or compared to the provision of economic incentives to acquire safety devices on one's own (Rowhani-Rahbar et al., 2016).

Another program, *The Emergency Department Counseling on Access to Lethal Means (ED CALM)*, trained psychiatric emergency clinicians in a large children's hospital to provide lethal means counseling and safe storage boxes to parents of patients under age 18 receiving care for suicidal behavior. In a pre-post quality improvement project, Runyan et al (2016) found that at post-test 76% (of the 55% of parents followed up, n=114) reported that all medications in the home were locked up as compared to fewer than 10% at the time of the initial emergency department visit. Among parents who indicated the presence of guns in the home at pre-test (i.e. 67%), all (100%) reported guns were currently locked up at post-test (C. W. Runyan et al., 2016).

- **Organizational policies and culture.** *Together for Life* is a workplace program of the Montreal Police Force implemented to address suicide among officers. Policy and program components were designed to foster an organizational culture that promoted mutual support and solidarity among all members of the Force. The program included training of supervisors, managers and all units to improve competencies in identifying suicidal risk and to improve use and awareness of existing resources. The program also included an education campaign to improve awareness and help-seeking (Mishara & Martin, 2012). Police suicides were tracked over 12 years and

compared to rates in the control city of Quebec. The suicide rate in the intervention group decreased significantly by 78.9% to a rate of 6.4 suicides per 100,000 population per year compared to an 11% increase in the control city (29.0 per 100,000) (Mishara & Martin, 2012).

Another example of this approach is the *United States Air Force Suicide Prevention Program (AFSPP)*. AFSPP included 11 policy and education initiatives and was designed to change the culture of the Air Force surrounding suicide. The program uses leaders as role models and agents of change, establishes expectations for behavior related to awareness of suicide risk, develops population skills and knowledge (i.e., education and training), and investigates every suicide (i.e., outcomes measurement). The program represents a fundamental shift from viewing suicide and mental illness solely as medical problem and instead sees them as larger service-wide problems impacting the whole community (K. L. Knox, Litts, Talcott, Feig, & Caine, 2003). Using a time-series design to examine the impact of the AFSPP program on various violence-related outcomes, researchers found that the program was associated with a 33% relative risk reduction in suicide (K. L. Knox et al., 2003). The program was also associated with relative risk reductions in related outcomes including moderate and severe family violence (30% and 54%, respectively), homicide (51%), and accidental death (18%) (K. L. Knox et al., 2003). A longitudinal assessment of the program over the period 1981 to 2008 (16 years before the 1997 launch of the program and 11 years post-launch) found significantly lower rates of suicide after the program was launched than before (K. L. Knox et al., 2010). These effects were sustained over time, except in 2004, which the authors found was associated with less rigorous implementation in that year than in the other years (K. L. Knox et al., 2010).

- **Community-based policies to reduce excessive alcohol use.** While multiple policies to limit excessive use of alcohol exist, several studies on alcohol outlet *density*, specifically, suggest that measures to reduce alcohol outlet density can potentially reduce alcohol-involved suicides. Additionally, a longitudinal analysis of alcohol outlet density, suicide mortality, and hospitalizations for suicide attempts over 6 years in 581 California zip codes indicated that the density of bars, specifically, is related to suicide and suicide attempts, particularly in rural areas (Johnson, Gruenewald, & Remer, 2009).

## Promote Connectedness

### Rationale

Sociologist, Emile Durkheim theorized in 1897 that weak social bonds, i.e. lack of connectedness, are among the chief causes for suicidality (Durkheim, 1897/1951). *Connectedness* is the degree to which an individual or group of individuals are socially close, interrelated, or share resources with others (Centers for Disease Control and Prevention, 2009). Social connections can be formed within and between multiple levels of the social ecology (Dahlberg & Krug, 2002), for instance between individuals (e.g. peers, neighbors, co-workers), families, schools, neighborhoods, workplace, faith communities, cultural groups, and society as a whole. Related to connectedness, *social capital* refers to a sense of trust in one's community and neighborhood, social integration, and also the availability and participation in social organizations (Beyer, Layde, Hamberger, & Laud, 2015; Muennig, Cohen, Palmer, & Zhu, 2013). Many ecological cross-sectional and longitudinal studies have examined the impact of aspects of social capital on depression symptoms, depressive disorder, mental health more generally, and suicide. While the evidence is still being built the pattern is towards a positive ~~n inverse~~ association between social capital measured by social trust, community/ neighborhood engagement, and improved mental health. Connectedness and social capital together can serve to protect against suicidal behaviors by decreasing isolation, encouraging adaptive coping behaviors, increasing belongingness, personal value and worth all of which helps individuals to build resilience in the face of adversity. Connectedness can also provide individuals with better access to formal supports and resources, mobilize communities to meet the needs of its members and provide collective primary prevention activities to the community as a whole (Centers for Disease Control and Prevention, 2009).

### Approaches

Promoting connectedness among individuals and within communities through modeling peer norms and enhancing community engagement can protect against suicide.

- **Peer norm approaches** seek to normalize prosocial behaviors/protective factors for suicide such as help-seeking, reaching out and talking to trusted adults, and promote peer connectedness. These approaches typically target youth and are delivered in school settings but can also be implemented in community settings.

**Comment [A]:** From JM: Seems like a nuance you can delete from this paragraph. You don't really pick up on this later and it probably requires more explanation

**Comment [A]:** From JH: Awkward wording. Consider, while the evidence is limited, existing studies suggest...

**Comment [A]:** From JM: This implies that prosocial behavior is currently abnormal. Maybe promote is a better word?

From JH: suggest deleting "seek to normalize" and say "Peer norm approaches encourage prosocial behavior..."

**Comment [A]:** I prefer to keep it as normalize and took out prosocial behavior. We want to normalize help-seeking versus making it seem like a personal weakness.

- **Community engagement activities.** Community engagement is an aspect of social capital. Community engagement approaches may involve residents participating in a range of activities, including religious activities, community clean-up and greening activities, and physical exercise. These activities provide opportunities for residents to become more involved in the community and to connect with other community members, organizations, and resources, resulting in enhanced overall physical health, reduced stress, and decreased depressive symptoms, thereby reducing risk of suicide.

### Potential Outcomes

- Reduction in maladaptive coping attitudes and behaviors
- Increase in healthy coping attitudes and behaviors
- Increase in referrals for youth in distressed
- Increase help-seeking behaviors
- Positive perception of adult support

### Evidence

Current evidence suggests that peer norm approaches and community engagement can reduce risk factors associated with suicidal behaviors.

- **Peer norm approaches.** Evaluations show that programs such as *Sources of Strength* can improve school norms and beliefs about suicide that are created and disseminated by student peers. In a randomized controlled trial of *Sources of Strength* conducted with 18 high-schools (6 metropolitan, 12 rural), Wyman et al. (2010) found that the program improved peer leaders' adaptive norms regarding suicide, their connectedness to adults, and school engagement. Peer leaders were also more likely than controls to refer a suicidal friend to an adult. Among students, the intervention increased perceptions of adult support for suicidal youths and the acceptability of seeking help. Perception of adult support increased most in students with a history of suicidal ideation. Finally, trained peer leaders also reported a greater decrease in maladaptive coping attitudes compared with untrained leaders (Wyman et al., 2010).
- **Community engagement activities.** A vacant lot greening initiative was undertaken in Philadelphia between 1999 and 2008. Local residents and community members worked together to green 4,436 lots (or 7.8 million square feet) in 4 areas of the city. Researchers found significant associated reductions in community residents' self-reported stress levels and engagement in more physical exercise than residents in control vacant lot areas. Other benefits included reductions in firearm assaults and vandalism (Branas et al., 2011).

**Comment [A]:** From JH: Cite findings from Let's Connect intervention program? While the intervention didn't significantly reduce suicidal behavior, there were significant improvements in connectedness (a protective factor for suicide).

**Comment [A]:** From TS: Is there any evidence on outcomes more proximal to suicide? Did they look for any and not find them? It is important to describe relevant null effects when they were found.

**Comment [A]:** From JM: Not seeing strong evidence here. Are you suggesting that this affects documented risk factors for suicide by reducing stress and increasing physical exercise? I would like to see a stronger evidence statement here.

From LLD: you might want to incorporate a phrase in the statement along the lines of "which are risk factors for suicide"

**Comment [A]:** From TS: They had a follow up paper in 2013 that showed intervention sites felt significantly safer. The effects on crimes was encouraging but not significant. It seems important to mention this too.

From LLD: not sure I agree with Tom's last point about mentioning the nonsignificant effect on crime.

## Teach Coping and Problem-Solving Skills

### Rationale

Building life skills prepares individuals to successfully tackle every day challenges and adapt to stress and adversity. Life skills encompasses many concepts, but most often include coping and problem-solving skills, conflict resolution, and critical thinking. Life skills are important in shielding individuals from suicidal behaviors (World Health Organization, 2014). Suicide prevention programs that focus on life and social skills training are drawn from social cognitive theories (Bandura, 1986), surmising that suicidal behavior is attributed to either direct learning, modeling, and environmental and individual (e.g. hopelessness) characteristics. The literature linking life skills and suicide is robust. The inability to employ adequate strategies to cope with immediate stressors or identify and find solutions for problems has been characterized among suicide attempters (Pollock & Williams, 2004). Treatments that include bolstering skills (Goldsmith, Pellmar, Kleinman, & Bunney, 2002) and include problem-solving techniques (Ghahramanlou-Holloway, Bhar, Brown, Olsen, & Beck, 2012; Townsend et al., 2001) appear to reduce suicidal ideation and attempts more effectively. Prevention programs focused on teaching these skills target youth, parents and families and have been used with both universal and at-risk populations. While many do not target suicidal behaviors directly, these programs strive to train youth and parents in important life skills to offset the underlying vulnerabilities that contribute to engaging in high-risk behaviors early in life.

**Comment [A]:** Specific edits needed here.

**Comment [A]:** From LLD: the word "either" here implies another comparative clause; should the word "or" be inserted before the word "modeling"? May want to just delete the word "either"

### Approaches

Current evidence provides support for the following two approaches:

- **Social emotional learning programs** focus on developing and strengthening communication and problem-solving skills, emotion regulation, conflict resolution, help seeking and coping skills. These approaches address a range of risk and protective factors for suicidal behavior. They provide children and youth with skills to resolve problems in relationships, school, and with peers, and help youth to address other negative influences (e.g., substance use) associated with suicide. These approaches are typically delivered to all students in a particular grade or school, although some programs also focus on groups of students considered to be at high risk for suicide. Opportunities to practice and reinforce skills are an important part of programs that work (Herman, Borden, Reinke, & Webster-Stratton, 2011).
- **Parenting skill and family relationship programs** are designed to strengthen parenting skills, enhance positive parent-child interactions, and improve children's behavioral and emotional skills and abilities. Several parenting and family relationship programs have been shown in rigorous evaluations to improve resilience and reduce risk factors for various behaviors, including

ones closely related to suicide, such as depression, internalizing behaviors, and substance abuse (M. S. Knox, Burkhart, & Hunter, 2010).

### Potential Outcomes

- Reduction in suicide attempts and suicide ideation
- Enhanced knowledge of risk and protective factors associated with suicide
- Reduction in suicide risk behaviors (i.e., depression, anxiety, conduct problems, substance abuse)
- Improve and normalize help-seeking behavior
- Enhance social competence and emotional regulation skills
- Enhance problem-solving and conflict management skills

### Evidence

There are several programs with evidence that support teaching social, emotional and parenting skills to reduce suicidal behaviors and associated risk factors.

- **Social emotional learning programs.** The *Youth Aware of Mental Health Program (YAM)* is a program developed for teenagers that uses interactive dialogue and role-playing to teach adolescents about the risk and protective factors associated with suicide (including knowledge about depression and anxiety) and enhances their problem-solving skills for dealing with adverse life events, stress, school and other problems. The program includes 3 hours of role-play sessions and interactive workshops combined with a booklet that students can keep, educational posters displayed in classroom, and interactive lectures about mental health at the beginning and end of the program (Wasserman et al., 2014). In a cluster-randomized controlled trial of YAM conducted across 10 European Union countries and 168 schools, students participating in the YAM program were significantly less likely to have an incident suicide attempt (OR 0.45, 95%CI 0.24–0.85;  $p=0.014$ ) and severe suicidal ideation (0.50, 0.27–0.92;  $p=0.025$ ) at the 12-month follow-up compared to the control group. Additionally, related to severe suicide ideation, in the YAM group absolute risk fell by 0.50% and relative risk fell by 49.6% (Wasserman et al., 2014).

*Signs of Suicide (SOS)* is another school-based prevention program for students aged 13–17. The program includes guided classroom discussions about suicide and depression. As part of the program, students are screened for depression and suicide risk and referred for professional help as indicated. The program is designed to increase knowledge about suicide and risk factors associated with suicidal behavior as well as improve and normalize help-seeking behavior (Schilling, Aseltine, & James, 2016). In a randomized controlled trial, SOS was shown to reduce self-reported suicide attempts at 3-months post intervention among

**Comment [A]:** From JH: Report ages (compare to SOS below)

**Comment [A]:** From JH: Suggest translating OR and 95% CI for wider audience.

From LLD: agree; this is too technical for a wider audience. See Tom's suggestion below.

**Comment [A]:** From JH: state if the control group received any kind of intervention

**Comment [A]:** From JH: significant?

**Comment [A]:** From TS: The Lancet paper has a 2015 publication date.

The authors provide the absolute and RR for suicide attempts too and they give a clear way of thinking about this – i.e., for RR “Of 1000 pupils, 11 attempted suicide in the control group vs five attempts in YAM”

It might be worth using the attempt example so you can provide this explanation.

**Comment [A]:** From JH: significant? Effect size/magnitude of reduction?

participating students compared to control students. The SOS program also increased students' knowledge of how to get help for themselves or friends for depression and/or suicidal thoughts, and favorable attitudes toward help-seeking. SOS participants with a lifetime history of suicide attempt were also less likely to report planning a suicide in the 3 months following the program compared to lower-risk participants (Schilling et al., 2016).

Finally, the *Good Behavior Game (GBG)* is a classroom-based program for elementary school children aged 6-10; it represents an example of upstream suicide prevention programming. The program uses a team-based behavior management strategy that promotes good behavior by setting clear expectations for good behavior and consequences for maladaptive behavior. The goal of the GBG is to create an integrated classroom social system that is supportive of all children being able to learn with little aggressive or disruptive behavior (Wilcox et al., 2008). In an outcome evaluation of the GBG, first graders assigned to GBG reported half the adjusted odds of suicidal ideation and suicide attempts. The beneficial effect of the program was consistent for suicidal ideation regardless of whether baseline covariates were included. The GBG effect on attempts was less robust in some adjusted models including caregiver mental health. In the second cohort of GBG students, neither suicidal ideation nor suicide attempts were significantly different between GBG and the control interventions (Wilcox et al., 2008). This finding likely arose due to the lack of implementation fidelity and pointed to the need for GBG to be delivered with precision, consistency, and teacher support. GBG was also found to be associated with reduced risk of later substance abuse, a risk factor for suicide (Kellam et al., 2008).

- **Parenting skill and family relationship programs.** Parenting and family skills training approaches have shown promising impacts in preventing key risk factors associated with suicide. For example, the *Incredible Years (IY)* is a comprehensive group training program for parents, teachers and children designed to reduce conduct and substance abuse problems, two important suicide risk factors, in youth by improving protective factors such as responsive and positive parent-teacher-child interactions and relationships, emotion self-regulation and social competence (all protective factors for suicide) (Herman et al., 2011). The program includes 9- 20 sessions offered in community-based settings (e.g., religious, recreation centers, mental health treatment centers, and hospitals). Several studies have demonstrated the effect of the IY program on reducing internalizing symptoms, such as anxiety and depression, and child conduct problems (C. H. Webster-Stratton, Reid, & Beauchaine, 2011; Webster-Stratton, Jamila Reid, & Stoolmiller, 2008). The program is also associated with improved problem-solving and conflict management; these skills were maintained at 1-year follow-up (Reid, Webster-Stratton, & Hammond, 2003; C. Webster-Stratton & Hammond,

**Comment [A]:** From JH: define control condition

**Comment [A]:** From JH: significant?

**Comment [A]:** From JH: Lower-risk? Do you mean students with no prior reported history of suicide attempts?

**Comment [A]:** From LLD: Jeff had questions about what is meant by upstream. You are referring to primary prevention but some of the other examples – YAM – are also primary prevention. Suggest just deleting this statement.

**Comment [A]:** From JH: compared to?

**Comment [A]:** From JH: Suggest stating clearly there are two separate cohorts of students receiving the intervention. How do these cohorts differ (time, location)?

**Comment [A]:** From TS: It is important to help the reader to understand that this study looked at the suicidal ideation when the first graders were age 19-21. This is not clear currently.

**Comment [A]:** From JH: Is this the authors' comment or your interpretation of the data? Please clarify.

1997; C. Webster-Stratton, Reid, & Hammond, 2001). The program demonstrated greater benefits as the dosage of the intervention increased (Herman et al., 2011).

Additionally, *Strengthening Families 10-14* is a program that involves sessions between parents, youth, and family with the goal of improving parents' skills for disciplining, managing emotions and conflict, and communicating with their children; promoting youths' interpersonal and problem-solving skills; and creating family activities to build cohesion and positive parent-child interactions. The premise of the program is that developing these skills for both parents and children will reduce internalizing behavior and adolescent substance abuse, two important risk factors for suicide (Spoth, Gyll, & Day, 2002). *Strengthening Families* has been shown to decrease externalizing behaviors, alcohol use, and drug use among youth participants and reductions in depression, alcohol use, and drug use among participating families (Spoth et al., 2002).

**Comment [A]:** From JH: significant? Also please define externalizing behaviors.

**Comment [A]:** From TS: This transition seems off.

## Identify and Support People At-Risk

### Rationale

In order to decrease suicide, attention to people at increased ~~or high~~-risk is necessary as these individuals tend to experience suicidal behavior at higher than average rates. These vulnerable or disadvantaged populations include, but are not limited to, individuals with lower socio-economic status or who are living with a mental health problem; people who have attempted suicide previously; individuals who are institutionalized, have been victims of violence, or are homeless; and members of certain racial and ethnic minority groups. Supporting these vulnerable groups requires proactive case finding along with access to, and retention in, mental health services. Finding effective ways of identifying at-risk or vulnerable groups, customizing services to make them accessible and engaged in care remain key challenges. For example, simply improving services does not guarantee that those services will be used by those most in need of them, nor will it necessarily increase the number of people who follow treatments that are recommended. People who are disadvantaged face social and economic issues that may adversely affect their ability to respond to the treatments or advice that are offered.

**Comment [A]:** From TS: This seems awkward as written. It might be better to say "...attention to people with specific vulnerabilities..."

**Comment [A]:** I prefer to use the standard language here.

### Approaches

The following three approaches focus on identifying and supporting people at increased risk.

- **Gatekeeper training** is designed to train teachers, coaches, providers and others in the community to identify people who may be at risk of suicide and to respond effectively, including facilitating treatment seeking and support services. Gatekeeper training is typically implemented in schools to identify at-risk youth and within health care settings to identify adults (and youth).
- **Screening combined with care management and overall continuity of care** has been used in primary care and behavioral health care settings to assure that people who may be at high-risk of suicide are identified and receive ongoing treatment as needed, particularly after inpatient discharge and other transitions within the healthcare system so they don't 'slip through the cracks'. These approaches typically employ screening for depression and/or suicide combined with collaborative treatment planning between patients and their providers and patient follow-up.
- **Crisis intervention.** These approaches provide support and referral services, typically by connecting a person in crisis (or a friend or family member of someone at-risk) to trained volunteers or professional staff via telephone hotline, online chat, or text messaging. Crisis intervention approaches are intended to impact key risk factors for suicide, including feelings of depression, hopelessness, and subsequent mental health care utilization. Like means reduction,

crisis interventions can put space or time between an individual who may be considering suicide and harmful behavior.

### Potential Outcomes

- Reduction in suicide attempts
- Reduction in suicide deaths
- Increased identification of individuals at-risk for suicidal behavior
- Increased at-risk individuals in treatment
- Increased community members trained to identify at-risk individuals
- Increased referrals for health care

### Evidence

~~There is evidence that community gatekeeper programs are successful in reducing suicides and suicide attempts but the efforts must be maintained (Substance Abuse and Mental Health Services Administration, 2014). However, there is limited evidence for effectiveness of screening programs, but at the same time, standard principles for public health screening make them promising (Pena & Caine, 2006). The number of studies evaluating crisis intervention services is limited, but a few studies do indicate that those who use the hotline services have decreased suicidal thoughts and behavior.~~

- **Gatekeeper training.** One example of gatekeeper training is the *Mental Health First Aid (MHFA)* program. This program is designed for the lay public and consists of three weekly sessions of three hours each. Participants learn the symptoms of people in mental health crises and/or in the early stages of mental health problems (i.e., those experiencing suicidal thoughts and behavior, acute stress reaction, panic attacks and acute psychotic behavior, and depression, anxiety, and psychotic disorders), possible risk factors, and where and how to get effective evidence-based effective help (Kitchener & Jorm, 2004). In a randomized controlled trial of 3010 participants of *MHFA*, the intervention group, compared to the wait-listed controls, reported significantly greater confidence in providing help to others, greater likelihood of advising people to seek professional help, improved concordance with health professionals about treatments, and decreased stigmatizing attitudes toward mental illness. Additionally, the intervention resulted in improved mental health of the participants themselves (Kitchener & Jorm, 2004). Additional research rigorously evaluating *MHFA* for its impact on intervention recipients' suicidal behavior is needed (Kitchener & Jorm, 2006).

Gatekeeper training has also been a core part of all *Garret Lee Smith (GLS) Suicide Prevention Program* which is in place in 49 states and 48 tribes. A multi-site evaluation assessed the

**Comment [A]:** From LLD: suggest shortening this introductory statement about the evidence and making it consistent with the other sections. If you need to provide caveats, then you might want to take a look at the YV TP for example wording.

**Comment [A]:** From TS: Add cites here. Also this wording is awkward because it could be read as suggesting that those who chose to use the hotline are different from others at risk who did not. Maybe you could add the follow up period to the end – they have decrease suicidal thoughts and behavior at xx

**Comment [A]:** From LLD: wording is a bit awkward here

**Comment [A]:** From JH: compared to?

**Comment [A]:** From JH: significant? Is it possible to report magnitude of intervention effects?

**Comment [A]:** From JH: Overall mental health or specific facets (e.g., depression, etc.)? Please clarify

connection between community gatekeeper training and a reduction of suicide attempts and deaths by comparing the change in suicide mortality rates and nonfatal suicidal behavior among the population aged 10-24 in counties implementing *GLS* trainings, with the trajectory observed in similar counties that did not implement these trainings. Counties implementing *GLS* trainings had significantly lower youth suicide rates the year following the training implementation (Walrath, Garraza, Reid, Goldston, & McKeon, 2015). This finding represents a decrease of 1 suicide death per 100,000 among youths 10 to 24 years of age or the avoidance of approximately 237 deaths in this age group between 2007 and 2010. Counties implementing *GLS* program activities also had significantly lower suicide attempt rates among youths 16 to 23 years of age in the year following implementation of the *GLS* program than did similar counties that did not implement *GLS* program activities (4.9 fewer attempts per 1000 youths; (Godoy Garraza, Walrath, Goldston, Reid, & McKeon, 2015)). More than 79,000 suicide attempts may have been averted during the period studied following implementation of the *GLS* program.

- **Screening combined with care management and overall continuity of care.** The *Henry Ford Perfect Depression Care* program was the pre-cursor to *Zero Suicide*, and its overall goal was to eliminate suicide. More broadly, though, the aim was to completely redesign depression care delivery to achieve breakthrough improvement in quality and safety by focusing on six aims: effectiveness, safety, patient centeredness, timeliness, efficiency, and equity among patients. The program developed concrete measures to assess progress on each of these aims and began with screening and assessment of each patient for suicide risk with coordinated continuous follow-up care system wide (C. E. Coffey, 2006). An examination of the impact of the *Henry Ford Perfect Depression Care (Pre-cursor to Zero Suicide)* program found that there was a dramatic and statistically significant decrease in the rate of suicide between the baseline years prior to the intervention (1999 and 2000) to the intervention years (2002-2009). During this time period, the suicide rate fell 82% (C. E. Coffey, 2006; C. E. Coffey, Coffey, & Ahmedani, 2013). Further, suicide rates also declined among HMO members who participated in targeted suicide prevention efforts and received mental health specialty services. However, for those HMO members who accessed only general medical services as opposed to specialty mental health services, the suicide rate increased (M. Coffey, Coffey, & Ahmedani, 2015).
- **Crisis intervention.** Suicide prevention hotlines are one way to provide crisis intervention. In an evaluation of the effectiveness of the *National Suicide Prevention Lifeline (NSPL)* to prevent suicide, 1,085 suicidal individuals who called the hotline completed a standard risk assessment for suicide, and 380 of those completed a follow-up assessment between 1 and 52 days after the initial assessment. Researchers found that over half of the initial sample were seriously considering suicide when they called, and they had a plan for their suicide. Researchers also found that participants experienced significant decreases in suicidality over the course of the

**Comment [A]:** From JM: I think you need to provide a little more context on Henry Ford so the readers understands in what kind of population the reductions were experienced. I assume from the end that Henry Ford is some sort of HMO, but just a little more information would help clarify this description to readers.

**Comment [A]:** From JH: how much?

**Comment [A]:** From JH: Report magnitude of decrease?

telephone session, and that levels of hopelessness and psychological pain continued to decrease after their initial call (Gould, Kalafat, Harrismunfakh, & Kleinman, 2007).

Comment [A]: From JH: how long?

In another study, this time employing a randomized controlled trial, Gould, Cross, Pisani, Munfakh, and Kleinman (2013) assessed the impact of the *Applied Suicide Intervention Skills Training (ASIST)*, a widely implemented training program that helps hotline counselors, emergency workers, and other gatekeepers to identify and connect with suicidal individuals, understand their reasoning for living and dying, and assist with safely connecting those in need to available resources. The training was evaluated across the NSPL network of hotlines over the period 2008-2009. Using data from 1,410 suicidal individuals who called 17 Lifeline centers, researchers found that compared to callers who spoke to counselors that received the usual care training, individuals who spoke with counselors trained in *ASIST* were significantly more likely to feel less depressed, less suicidal, less overwhelmed, and more hopeful by the end of their call to the hotline. Counselors trained in *ASIST* were also more skilled at keeping callers on the phone longer and establishing a connection with them. However, training in *ASIST* did not result in more comprehensive suicide risk assessments than usual care training (Gould et al., 2013).

## Intervene to Lessen Harms and Prevent Future Risk

### Rationale

Individuals who have experienced mental health challenges, suicidal ideation, who have made suicide attempts or engaged in non-suicidal self-injury are at increased risk of suicide (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012). Risk of suicide can also increase among those who have lost a friend, family member, co-worker, or other acquaintance to suicide (Pitman, Osborn, King, & Erlangsen, 2014). Exposure to sensationalized or uninformed reporting regarding on suicide may heighten the risk of suicide among vulnerable individuals and can inadvertently contribute to suicide contagion (Etzersdorfer & Sonneck, 1998; Niederkrotenthaler & Sonneck, 2007).

### Approaches

A broad array of approaches to lesson harms and reduce future risk of suicide among those at increased risk include the provision of mental health care and improved continuity of care, improving linkage to care through active post-discharge planning and follow-up that decreases barriers to ongoing therapeutic support, increasing connectedness to supportive others, addressing bereavement, and framing communications to emphasize resilience, decrease negative affect, and to prevent contagion.

- **Treatment for people at-risk of suicide** typically includes various forms of psychotherapy delivered by licensed providers to help individuals with mental health problems and other risk factors for suicide with problem-solving, impulsivity and emotion regulation.
- **Treatment to prevent re-attempts.** These approaches typically include follow-up contact and use diverse modalities (e.g., home visits, mail, telephone, e-mail) to engage recent suicide attempt survivors in continued treatment to prevent re-attempts. Treatment may focus on improved coping skills, mindfulness, and other emotional regulation skills, and may include case management home visits to increase adherence to treatment and continuity of care; and one-on-one interpersonal therapy and/or group therapy. Approaches that engage and connect attempters to peers and providers are especially important because many attempters do not present to aftercare; 12%-25% reattempt within a year, and 3%-9% of attempt survivors die by suicide within 1 to 5 years of their initial attempt (Inagaki et al., 2015)
- **Postvention** approaches are implemented *after* a suicide has taken place and may include debriefing sessions, counseling, and/or bereavement support groups for surviving friends and family members/loved ones. These programs have not typically been evaluated for their impact on suicide or suicidal behavior but may reduce survivors' guilt, feelings of depression, and complicated grief (Szumilas & Kutcher, 2011).

**Comment [A]:** From LLD: simplify statement and make it consistent with the other introductory statements about approaches. You may also want to take a look at the introductory statements to this section in the other TPs.

**Comment [A]:** From LLD: Suggest fleshing this description out a bit. You may want to mention how these are typically delivered (e.g., one on one or group formats; typical number of sessions, location, etc.).

- **Safe messaging following a suicide.** The manner in which information on a recent suicide is communicated to the public (e.g. school assemblies, mass media, social media) can heighten the risk of suicide among vulnerable individuals and can inadvertently contribute to suicide contagion. Therefore, responsible and safe reporting may help prevent suicide and suicide contagion.

**Comment [A]:** From JH: add something about contagion?

### Potential Outcomes

- Reduction in mental health-related sequelae
- Increase connectedness
- Improved coping skills
- Improved messaging following suicide
- Reduction in re-attempts

### Evidence

The evidence addressing strategies to lesson harm and prevent future risk of suicide includes the evaluation of effects of specific approaches on risk and protective factors as well as suicide-related mortality. However, because the evaluation of suicide-related mortality requires large sample sizes and extended follow-up, much of the evidence in this area primarily focuses on risk and protective factors.

- **Treatment for people at-risk of suicide.** There are a number of treatments with evidence of impact on risk and protective factors for suicide. One example is the *Improving Mood – Promoting Access to Collaborative Treatment (IMPACT)* program. *IMPACT* aims to prevent suicide among older primary care patients by reducing suicide ideation and depression in primary care settings. It facilitates the development of a therapeutic alliance, a personalized treatment plan that includes patient preferences, as well as proactive follow-up (biweekly during an acute phase and monthly during continuation phase) by a depression care manager (Hunkeler et al., 2006). The program has been shown to significantly improve quality of life, and to reduce functional impairment, depression and suicidal ideation over 24-months of follow-up (Hunkeler et al., 2006; Unutzer et al., 2006) relative to patients who received care as usual.

Another example is *Collaborative Assessment and Management of Suicidality (CAMS)*, which is a therapeutic approach for suicide-specific assessment and treatment of patient's suicide risk. This flexible approach can be used across treatment settings and clinician theoretical orientations and involves the clinician and patient working together in an interactive assessment process to develop patient-specific treatment plans. *CAMS* sessions are collaborative and involve constant

patient about what is and is not working with the ultimate goal of enhancing the therapeutic alliance and increasing treatment motivation in the suicidal patient. CAMS been tested and supported in 6 correlational studies (Jobes, 2012), in a variety of inpatient and outpatient settings and in one RCT with several additional RCTs under way. CAMS has been associated with significant improvements in suicidal ideation, overall symptom distress, and feelings of hopelessness at 12 month follow-up among a community-based sample of suicidal outpatients. (Comtois et al., 2011).

Other examples include *Dialectical Behavioral Therapy (DBT)* and *Attachment-Based Family Therapy (ABFT)*. DBT is a multicomponent therapy for individuals at high risk for suicide and who may struggle with impulsivity and emotional regulation. The components of DBT include individual therapy, group skills training, between-session telephone coaching and a therapist consultation team. In a randomized controlled trial of women with recent suicidal or self-injurious behavior, those receiving DBT were half as likely to make a suicide attempt at two-year follow-up than women receiving community treatment (23% vs 46%), required less hospitalization for suicide ideation, and had lower medical risk across all suicide attempts and self-injurious acts combined (Linehan et al., 2006).

ABFT is a program for adolescents aged 12-18 and is designed to treat clinically diagnosed major depressive disorder, eliminate suicidal ideation, and reduce dispositional anxiety (Diamond et al., 2010). A randomized controlled trial of ABFT found that suicidal adolescents assigned to ABFT experienced significantly greater improvement in suicidal ideation over 24 weeks of follow-up than did adolescents assigned to enhanced usual care. Additionally, a significantly higher percentage of ABFT participants reported no suicidal ideation in the week prior to assessment at 12 weeks than did adolescents receiving enhanced usual care (69.2% vs. 34.6%) and at 24 weeks (82.1% vs. 46.2%) (Diamond et al., 2010).

- **Treatment to prevent re-attempts.** Several strategies that aim to prevent re-attempts have demonstrated impact on reducing suicidal behavior. For example, *Emergency Department Brief Intervention with Follow-up Visits* is a program that involves a one-hour discharge information session that addresses suicidal behavior, distress, risk and protective factors, alternatives to suicidal behavior, and referral options, combined with nine follow-up contacts over 18 months (at 1, 2, 4, 7, 11 weeks and 4, 6, 12, 18 months). Follow-up contacts are either conducted by phone or through home visits according to a specific time line for up to 18-months. A randomized controlled trial that enrolled suicide attempters from eight hospital emergency departments in five culturally different sites found that a brief intervention combined with 9 follow-up visits over 18-months was associated with significantly fewer deaths from suicide relative to a treatment-as-usual group (0.2% versus 2.2%, respectively) (Fleischmann et al., 2008).

**Comment [A]:** From TS: I think a word is missing – "patient input"?

**Comment [A]:** From JH: Unclear. According to the article, this program was evaluated in five countries. Please state the countries. Thnx.

Another example of treatment to prevent re-attempts involves *active follow-up contact approaches* such as postcards, letters, and telephone calls intended to increase a patient's sense of connectedness with health care providers and decrease isolation. These approaches include expression of care and support and typically invite patients to reconnect with their provider. Contacts are made periodically (e.g., monthly or every few months in the first 12 months post-discharge with some programs continuing contact for two or more years). In a meta-analysis conducted by Inagaki et al. (2015), interventions to prevent repeat suicidal behavior in patients admitted to an emergency department for suicide attempt were found to reduce reattempts by approximately 17% for up to 12 months post-discharge; however, the **long-term effects** of these approaches on reattempts has not yet been demonstrated. Also, because the number of trials and associated sample sizes included in this meta-analysis were small, it was not possible to determine the effect of active contact and follow-up approaches on death by suicide. In a randomized controlled trial of the post-crisis suicide prevention **long-term** follow-up contact approach, Motto and Bostrom (2001) found that patients who refused ongoing care but who were randomized to be contacted by letter four times per year had a lower rate of suicide over two years of follow-up than did patients in the control group who received no further contact. Other studies have also shown post-crisis letters and coping cards to be protective against suicide ideation and attempts (Hassanian-Moghaddam, Sarjani, Kolahi, & Carter, 2011; Wang et al., 2016).

Finally, *Cognitive Behavior Therapy for Suicide Prevention (CBT-SP)* is an example of a therapeutic approach to prevent re-attempts. It uses a risk-reduction, relapse prevention approach that includes an analysis of proximal risk factors and stressors (e.g., relationship problems, school or work-related difficulties) leading up to and following the suicidal event; safety plan development; skill building; and psychoeducation. *CBT-SP* also has family skill modules focused on family support and communication patterns as well as improving the family's problem solving skills. A randomized controlled trial of *CBT-SP* found that 10-session outpatient cognitive therapy designed to prevent repeat suicide attempts resulted in a 50% reduction in the likelihood of a suicide reattempt among adults who had been admitted to an emergency department for a suicide attempt relative to treatment as usual (Brown et al., 2005).

- **Postvention** programs are implemented with the goal of providing support to survivors of others' suicide to reduce their own risk of suicide. One example of a postvention program, *StandBy Response Service (StandBy)*, provides clients with face-to-face outreach and telephone support through a professional crisis response team. Site coordinators develop customized case management plans, referring clients to other existing community services matched to their needs (Visser, Comans, & Scuffham, 2014). In a study by Visser et al. (2014), *StandBy* clients were significantly less likely to be at high risk for suicidality than a suicide bereaved comparison group

Comment [A]: From JH: Define (follow-ups greater than 1 year)

Comment [A]: From JH: Define

who had not had contact with the *StandBy* program (48% and 64% respectively). Additionally, research suggests that active postvention approaches in which outreach to suicide survivors occurs at the scene of a suicide is associated with intake into treatment sooner, greater attendance at support group meetings, and attendance at more meetings compared to passive postvention (versus passive approaches where survivors self-refer for services) (J. Cerel & Campbell, 2008).

- **Safe messaging following a suicide.** Safe messaging after a suicide can help assure that reporting of the event is done in such a way to reduce risk to consumers of news media and other messaging who may be particularly vulnerable. One way to ensure safe messaging following a suicide is to encourage that reporters adhere to *media guidelines for reporting on suicides*. Reports that are both inclusive of suicide prevention messages, stories of hope and resilience, risk and protective factors, and links to helping resources (e.g., hotline) and that avoid sensationalizing events or reducing suicide to one cause can help reduce the likelihood of suicide contagion. The most compelling evidence supporting the effect of *media guidelines* on reduction in suicides comes from Austria. After a sharp increase in suicides on the Viennese subway, media guidelines were introduced and an interrupted time series design was used to evaluate the national impact of the guidelines on subsequent suicides. Changes in the quality and quantity of media reporting resulted in a significant reduction of 81 suicides annually in the Viennese subway system (Niederkrötenhaler & Sonneck, 2007).

**Comment [A]:** From TS: Don't you mean "Recommendations for Reporting on Suicide"?  
Please cite:  
<http://afsp.org/wp-content/uploads/2016/01/recommendations.pdf>

The media did not want "guidelines" and they reacted negatively to the idea of external guidelines.

**Comment [A]:** From TS: Are you sure that the 81 reduction was just on the subway system? I thought that was nationally. Please confirm.

**Comment [A]:** From JH: other evaluations available?

**Comment [A]:** From TS: Thomas also had a 2010 report that suggested benefits of good reporting.

## Sector Involvement

Public health can play an important and unique role in addressing suicide. Public health agencies, which typically place prevention at the forefront of efforts and work to create broad population-level impact, can bring critical leadership and resources to bear on this problem. For example, these agencies can serve as a convener, bringing together partners and stakeholders to plan, prioritize, and coordinate suicide prevention efforts. Public health agencies are also well positioned to collect and disseminate data, implement preventive measures, evaluate programs, and track progress. Although public health can play a leadership role in preventing suicide, the strategies and approaches outlined in this technical package cannot be accomplished by the public health sector alone. As noted in the National Strategy to Prevent Suicide, the integration and coordination of prevention activities across sectors and settings is critical for expanding the reach and impact of suicide prevention efforts.

Other sectors vital to implementing this package include, but are not limited to, education, government (local, state, and federal), social services, health services, business, labor, justice, housing, media, and organizations that comprise the civil society sector such as faith-based organizations, youth-serving organizations, foundations, and other non-governmental organizations. Collectively, these sectors can make a difference in preventing suicide by impacting the various contexts and underlying risks that contribute to suicide.

The strategies and approaches described in this technical package are summarized in Appendix A along with the relevant sectors that are well positioned to lead implementation efforts. For example, business and labor, health care insurers and providers, and government entities are in the best position to implement programs and policies that *Strengthen Economic Supports and Access to Mental Health Care*. These types of supports go beyond individual behavior change and require commitment and support from those sectors that can directly address some of the underlying risks and the environmental contexts that increase the risk for suicide. Public health entities can play an important role by gathering and synthesizing information to inform policy, raise awareness, and evaluate the effectiveness of various policies. Moreover, partnerships with non-governmental and community organizations can be instrumental in increasing awareness of and garnering support for policies affecting individuals and families.

The public health sector has been at the forefront of many community-based prevention efforts, working collaboratively with schools and community-based organizations, to change social norms and positively impact health behavior. Public health is well suited to take on a similar leadership role in *Promoting Connectedness* through peer norm and community engagement activities and supporting the development, evaluation, and adoption of effective programs that *Teach Coping and Problem-Solving Skills* to prevent suicide from happening in the first place. These programs are often delivered in school and community settings, making education and non-governmental organizations vital partners in prevention.

Businesses, workplaces, and local and state government entities, on the other hand, are in the best position to establish policies and support practices that *Create Protective Environments* where people live, work, and play. Public health entities can play an important role by gathering and synthesizing information, working with other agencies within the executive branch of their state or local government in support of policy and other approaches, and evaluating the effectiveness of measures taken. In a similar fashion, public health entities can partner with schools, workplaces, and community organizations to implement and evaluate prevention programs, policies and practices geared toward creating safe, healthy, and supportive environments.

Finally, this technical package includes a number of interventions delivered in hospital, primary care, behavioral health care, and community settings designed to *Identify and Support People At-Risk* and to *Lessen Harms and Prevent Future Risk*. The intensity and activities of these interventions require the expertise of professionals who are licensed and trained to deliver critical intervention support. The health care, social services, and justice sectors can work collaboratively to support individuals at high-risk for suicide and their families. These activities also require coordination of supports across various service providers and community organizations.

Regardless of strategy, action by many sectors will be necessary for the successful implementation of this package. In this regard, all sectors can play an important and influential role in preventing suicide from happening in the first place and lessening the immediate and long-term harms of suicidal behavior by helping those in times of crisis get the services and support they need.

## Monitoring and Evaluation

Monitoring and evaluation are necessary components of the public health approach to prevention. It is important to have timely and reliable data to monitor the extent of the problem and to evaluate the impact of prevention efforts. Data are necessary for program implementation as planning, implementation, and assessment all rely on accurate measurement of the problem.

Surveillance data helps researchers and practitioners track changes in the burden of suicide. Surveillance systems exist at the federal, state, and local levels. It is important to assess the availability of surveillance data and data systems across these levels to identify and address gaps in the systems. CDC's National Vital Statistics System and the National Violent Death Reporting System (NVDRS) are examples of surveillance systems that provide data on deaths from suicide. NVDRS, for example, is a state-based surveillance system that combines data from death certificates, law enforcement reports, and coroner or medical examiner reports to provide detailed information on the circumstances of violent deaths, including suicide, which can assist communities in guiding prevention approaches (Blair, Fowler, Jack, & Crosby, 2016). The National Electronic Injury Surveillance System-All Injury Program (NEISS-AIP) provides nationally representative data about all types and causes of nonfatal injuries treated in U.S. hospital emergency departments, and can be used to assess national rates of, and trends in, self-harm injuries by cause (e.g., falls, poisoning, etc.), age, race/ethnicity, sex, disposition (where the injured person goes when released from the Emergency Department).

In addition to information on deaths and nonfatal injuries, there are also surveillance systems that provide national, state, and some local estimates of suicidal behavior. The Youth Risk Behavior Surveillance System (YRBSS) collects information from a nationally representative sample of 9-12 grade students and is a key resource in monitoring health-risk behaviors among youth, including whether youth have seriously considered attempting suicide, attempted suicide, made a plan, or required treatment by a doctor or nurse for a suicide attempt that resulted in an injury, poisoning, or overdose (Brener et al., 2013). The YRBSS data are obtained from a national school-based survey conducted by CDC as well as from state, territorial, tribal, and large urban school district surveys conducted by education and health agencies. The National Survey on Drug Use and Health (NSDUH) is an annual nationwide survey of individuals aged 12 years and older that provides national and state-level estimates of drug use and mental health-related issues, including suicide ideation and suicide attempts.

It is also important at all levels (local, state, and federal) to address gaps in responses, track progress of prevention efforts and evaluate the impact of those efforts, including the impact of this technical package. Evaluation data, produced through program implementation and monitoring, is essential to provide information on what does and does not work to reduce rates of suicide and its associated risk and protective factors. Theories of change and logic models that identify short, intermediate, and long-term outcomes are an important part of program evaluation.

**Comment [A]:** From TS: This description seems incomplete compared to the description of YRBS

The evidence-base for suicide prevention has advanced greatly over the last few decades. However, additional research is needed to understand the impact of programs, policies, and practices on preventing suicide and suicide attempts, as opposed to merely examining the effectiveness of programs to impact risk factors associated with suicide. More research is also needed to examine the effectiveness of upstream and community-level strategies to prevent suicide at the population level. Lastly, it will be important for researchers to test the effectiveness of combinations of the strategies and approaches included in this package. Most existing evaluations focus on approaches implemented in isolation, but there is potential to understand the synergistic effects within a comprehensive prevention approach. ~~Additional research is needed to understand the extent to which combinations of strategies and approaches result in greater reductions in suicide than individual programs, practices, or policies.~~

**Comment [A]:** From TS: Should this be programs, policies, and practices to be consistent?

**Comment [A]:** From JH: including attempts?

**Comment [A]:** From JH: redundant with prior sentence.

**Comment [A]:** From TS: I found this somewhat awkward. The idea of suicide struggling seemed off and the point is not entirely clear. I think you can be more specific and reference an earlier point in the media recommendations section.

**Comment [A]:** From JH: Upstream/downstream is jargon.

**Comment [A]:** From TS: I think you can drop this and just use the more descriptive text. You don't need both. You could describe this as a range.

## Conclusion

Suicide is a serious public health problem whose rates have been on the rise for more than a decade and whose costs stretch well into the billions of dollars each year. While suicide is a rare outcome statistically, its human impact has a ripple effect that is far-reaching. Each of us likely interacts with suicide survivors, those with lived experience, and those with thoughts of suicide, on a daily basis--at home, at work, and in our communities. Suicide and suicide attempts are therefore public health issues of societal concern. Fortunately, like many public health problems, suicide is preventable, and fortunately more is being done to prevent suicide than ever before, as evidenced by the work of the National Action Alliance for Suicide Prevention, the release of the first world report on suicide, and more timely surveillance data, to name just a few examples. Unfortunately and unlike most other public health problems, suicide still struggles against stigma, shame, and secrecy related to help-seeking, mental illness, being a survivor, or someone with lived experience; misplaced fear of asking someone about their risk of suicide (versus the fear and consequence of not asking), and fear of taking up certain strategies known to be effective but perhaps unpopular; misinformation about suicide preventability, and disproportionate funding given the public health burden. Suicide also struggles against the right degree of awareness where too much information, for example by well-meaning reporters and others, may actually do harm.

In an effort to continue pushing the field and society further towards prevention, this technical package includes strategies and approaches that ideally would be used in a comprehensive fashion, in combination--in a multi-level, multi-sectoral way. This technical package includes strategies and approaches targeting upstream prevention (e.g., social emotional learning for children and youth), as well as strategies focused more downstream (e.g., cognitive behavioral treatment to prevent re-attempts). It includes universal, selective, and indicated strategies, or strategies that focus on the whole population regardless of risk to strategies that focus on those groups at highest risk. Importantly, this technical package extends the bounds of the typical prevention strategies to consider approaches at the

(outer levels of the social ecology), e.g., policies to stabilize housing and community engagement initiatives.

While the evidence base continues to emerge, the collection of programs, policies, and practices laid out here are available for implementation now. And in keeping with good public health practice, the intent is that monitoring and evaluation will play a key role in that implementation. Moreover, as new evidence becomes available, this technical package can be refined to reflect the current state of the science.

In closing, and in keeping with a message of resilience as spoken by those with lived experience, 'hope, help, and healing is possible.'

**Comment [A]:** From JM: Yes this is jargon, so the e.g., helps, but you might want to figure out a way to say this without referring to the outer levels of the social ecology.

**Comment [A]:** This sets you up for people to say oh yeah what about... AI/AN, transgendered people, prisoners etc.

	<i>StandBy Response Service</i>		✓		
	<b>Safe messaging following a suicide</b>				Public Health
	<i>Media Guidelines</i>	✓			Media

<sup>1</sup>This column refers to the lead sectors well positioned to bring leadership and resources to implementation efforts. For each strategy, there are many other sectors such as non-governmental organizations that are instrumental to prevention planning and implementing the specific programmatic activities.

**Policies, Programs, and Practices to Support  
Individuals, Families, & Communities:**

**A Technical Package to Prevent Suicide**

**Comment [A]:** From TS: “support” could be read in a very limited way – e.g., providing services. This seems inconsistent with our emphasis on upstream approaches and work across the ecology.

**Comment [A]:** From JM: The term support evokes a specific strategy. Some of what is contained in this package goes beyond support or takes other avenues such as many of the approaches within protective environments. Is there another broader word that could be used to characterize this package here?

## Overview

This technical package represents a select group of strategies based on the best available evidence to help communities and states sharpen their focus on prevention activities with the greatest potential to prevent suicide. These strategies include strengthening economic supports; strengthening access to mental health care; creating protective environments; promoting connectedness; teaching coping and problem-solving skills; identifying and supporting people at-risk; and intervening to lessen harms and prevent future risk. The strategies represented in this package include those with a focus on preventing suicide from happening in the first place as well as approaches to lessen the immediate and long-term harms of suicidal behavior for individuals, families, communities, and society. The strategies in the technical package support the goals and objectives of the National Strategy for Suicide Prevention and the National Action Alliance for Suicide Prevention's priority to strengthen community-based prevention. Commitment, cooperation, and leadership from numerous sectors, including public health, education, justice, health care, social services, business, labor, and government can bring about the successful implementation of this package.

### What is a Technical Package?

A technical package is a compilation of a core set of strategies to achieve and sustain substantial reductions in a specific risk factor or outcome (Frieden, 2014). Technical packages help communities and states prioritize prevention activities based on the best available evidence. This technical package has three components. The first component is the **strategy** or the preventive direction or actions to achieve the goal of preventing suicide. The second component is the **approach**. The approach includes the specific ways to advance the strategy. This can be accomplished through *programs, policies, and practices*. The approaches included come primarily from studies based in the United States. The **evidence** for each of the approaches in preventing suicide or its associated risk factors is included as the third component. This package is intended as a resource to guide and inform prevention decision-making in communities and states.

### Preventing Suicide is a Priority

Suicide, as defined by the Centers for Disease Control and Prevention (CDC), is part of a broader class of behavior called *self-directed violence*. Self-directed violence refers to behavior directed at oneself that deliberately results in injury or the *potential* for injury (Crosby, Ortega, & Melanson, 2011). Self-directed violence may be *suicidal* or *non-suicidal* in nature. For the purposes of this document, we refer only to behavior where suicide is intended:

- **Suicide** is a death caused by self-directed injurious behavior with any intent to die as a result of the behavior.

- **Suicide attempt** is defined as a *non-fatal* self-directed and potentially injurious behavior with any intent to die as a result of the behavior. A suicide attempt may or may not result in injury.

**Suicide is highly prevalent.** Suicide presents a major challenge to public health in the United States and worldwide. It contributes to premature death, morbidity, lost productivity, and health care costs (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014). In 2014 (the most recent year of available death data), suicide was responsible for 42,773 deaths in the U.S., which is approximately one suicide every 12 minutes (Centers for Disease Control and Prevention, 2016d). In 2014, suicide ranked as the 10th leading cause of death and has been among the top 12 leading causes of death since 1975 in the U.S (Centers for Disease Control and Prevention, 2016d). Overall suicide rates have increased 24% from 1999 to 2014 (Curtin, Warner, & Hedegaard, 2016). ~~Suicide is a problem throughout the life span; it is the second leading cause of death among those aged 10–3419 years, also second among persons in their 20s and 30s; it is the fourth leading cause among persons in their 40s and seventh among persons in their 50s~~ (Centers for Disease Control and Prevention, 2016d)).

Suicides reflect only a portion of the problem (Crosby, Han, Ortega, Parks, & Gfroerer, 2011). Substantially more people are hospitalized as a result of nonfatal suicidal behavior (i.e. suicide attempts) than are fatally injured, and an even greater number are either treated in ambulatory settings (e.g., emergency departments) or not treated at all (Crosby, Han, et al., 2011). For example, during 2014, among adults aged 18 years and older, for every one suicide there were 9 adults treated in hospital emergency departments for self-harm injuries, 27 who reported making a suicide attempt, and over 227 who reported seriously considering suicide (i.e. ideation) (Ferdon et al., In press).

**Suicide is associated with several risk and protective factors.** Suicide, like other human behaviors, is ~~complex with~~ has no single determining cause. Instead, suicide occurs in response to multiple biological, psychological, interpersonal, environmental and societal influences that interact with one another, often over time. The social-ecological model-- encompassing multiple levels of focus from the individual, relationship, community, and societal-- is a useful framework for viewing and understanding suicide risk factors identified in the literature (Dahlberg & Krug, 2002). Risk and protective factors for suicide exist at each level. For example, risk factors include:

- **Individual level:** History of depression and other mental illnesses, hopelessness, alcohol and drug abuse, previous suicide attempt, violence ~~victimization~~, and genetic and biological determinants
- **Relationship level:** High conflict or violent relationships, sense of isolation and lack of social support, family/loved one's history of suicide, financial and work stress
- **Community level:** Inadequate community connectedness, barriers to health care (e.g., lack of access to providers and medications)

**Comment [A]:** Add AI/AN stats, racial/ethnic stats

**Comment [A]:** From JM: Seems like too much detail on leading causes, suggest looking for a way to condense. See suggested edit.

**Comment [A]:** It might be helpful to balance the description of suicide as complex with multiple influencers with a positive message about this meaning that there are multiple opportunities for prevention. We don't want readers to think we need to address all of the complex factors to make a difference.

**Comment [A]:** From JH: Is it worth mentioning terminal disease or condition?

**Comment [A]:** From TS: Could broaden this to include perpetration too.

- **Societal level:** Availability of lethal means of suicide, unsafe media portrayals of suicide, stigma associated with help-seeking and mental illness (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014).

It is important to recognize that the vast majority of individuals who are depressed or who have other risk factors noted, do *not* die by suicide. Furthermore, the relevance of each risk factor can vary by age, race, gender, sexual orientation, residential geography, and socio-cultural and economic status (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014).

Protective factors, or those influences that guard *against* the risk for suicide, can also be found across the different levels of the social-ecological model. Protective factors identified in the literature include: effective coping and problem solving skills, moral objections to suicide, strong and supportive relationships with partners, friends, and family; connectedness to school, community and other social institutions; availability of quality and ongoing physical and mental health care, and reduced access to lethal means (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012; World Health Organization, 2014). These protective factors can either counter a specific risk factor or guard against a number of risks associated with suicide.

**Suicide is connected to other forms of violence.** Suicide and other forms of violence often share some of the same root causes (Butchart, Phinney, Check, & Villaveces, 2004; Kleven, Simon, & Chen, 2012). For example, in neighborhoods where there is low social cohesion, or where residents don't support and trust each other, people are at higher risk for suicide (Desai, Dausey, & Rosenheck, 2005) as well as perpetration of child maltreatment (Coulton, Crampton, Irwin, Spilsbury, & Korbin, 2007; Freisthler, Merritt, & LaScala, 2006), teen dating violence (Capaldi, Noble, Shortt, & Kim, 2012), intimate partner violence (Pinchevsky & Wright, 2012), and youth violence (Sampson, Morenoff, & Gannon-Rowley, 2002). Additionally, a lack of economic opportunities and unemployment are associated with suicide (Luo, Florence, Quispe-Agnoli, Ouyang, & Crosby, 2011; Reeves et al., 2012), as well as perpetration of child maltreatment (D. Runyan, Wattam, Ikeda, Hassan, & Ramiro, 2002), intimate partner violence (Heise & Garcia-Moreno, 2002; Pinchevsky & Wright, 2012), sexual violence (Centers for Disease Control and Prevention, 2016c) and youth violence (Wilson, 2011). Other shared risk factors for suicide and violence occur at the individual level and include substance abuse, mental health problems, witnessing violence, and a lack of problem-solving skills (Centers for Disease Control and Prevention, 2016a, 2016c, 2016e; U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012).

Just as risk factors may be shared across suicide and violence, so too may protective factors overlap. For example, **connectedness increases individual's and communities' resilience to suicide and other forms of violence, including connectedness to one's community** (Basile, Hamburger, Swahn, & Choi, 2013; Borowsky, Hogan, & Ireland, 1997; Centers for Disease Control and Prevention, 2016b; Coulton et al.,

**Comment [A]:** From TS: I found this wording somewhat awkward.

2007; Kleiman, Riskind, Schaefer, & Weingarden, 2012; Pinchevsky & Wright, 2012; Widome, Sieving, Harpin, & Hearst, 2008), school (Basile, Espelage, Rivers, McMahon, & Simon, 2009; Capaldi et al., 2012; Carter, McGee, Taylor, & Williams, 2007; DeGue et al., 2013; Hong, Kral, Espelage, & Allen-Meares, 2012; Losel & Farrington, 2012), family (Capaldi et al., 2012; Centers for Disease Control and Prevention, 2016a; Elgar, Craig, Boyce, Morgan, & Vella-Zarb, 2009; Maimon, Browning, & Brooks-Gunn, 2010; Resnick, Ireland, & Borowsky, 2004), caring adults (Capaldi et al., 2012; Losel & Farrington, 2012; Maimon et al., 2010), and pro-social peers (Capaldi et al., 2012; Losel & Farrington, 2012).

**The health and economic consequences of suicide are substantial.** Suicide and suicide attempts have far-reaching consequences for individuals, families, and communities (Dunne, McIntosh, & Dunne-Maxim, 1987; Mishara, 1995; National Action Alliance for Suicide Prevention: Suicide Attempt Survivors Task Force, 2014; National Action Alliance for Suicide Prevention: Survivors of Suicide Loss Task Force, 2015). By one conservative estimate, for every death by suicide six people are directly impacted (i.e. survivors). Based on this figure it is estimated that there are over 13 million survivors in the U.S. and unfortunately, survivorship itself is a risk factor for suicide (Crosby & Sacks, 2002). Research indicates that the health consequences of violence, including suicide, are also much more extensive than injury and death. Suicide attempt survivors (i.e. those with lived experience) may suffer long-term health and mental health consequences ranging from anger, guilt, and physical impairment, depending on the means and severity of the attempt (Chapman & Dixon-Gordon, 2007). Similarly, survivors of a loved one's suicide may experience ongoing pain and suffering including complicated grief (Mitchell, Kim, Prigerson, & Mortimer-Stephens, 2004), stigma, depression, anxiety, post-traumatic stress disorder, and increased risk of suicidal ideation and suicide (Julie Cerel, McIntosh, Neimeyer, Maple, & Marshall, 2014; Sudak, Maxim, & Carpenter, 2008).

The economic toll of suicide is immense as well. The total lifetime costs associated with nonfatal injuries and deaths caused by self-directed violence in 2013 were approximately \$93.5 billion after adjusting for under-reporting of suicide (Shepard, Gurewich, Lwin, Reed, & Silverman, 2016). The overwhelming burden of these costs results from lost productivity over the life course, with the average cost per suicide being over \$1.3 million (Shepard et al., 2016).

**Suicide can be prevented.** Despite the myths surrounding suicide, like most public health problems, suicide is preventable (U.S. Public Health Service, 1999). And while progress will continue to be made into the future, evidence for numerous programs, practices, and policies currently exists, and many programs are ready to be implemented now. Just as suicide is not caused by a single factor, research suggests that suicide will not be prevented by any single intervention taking place in any single setting (Silverman & Maris, 1995; U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012). Rather, suicide prevention is best achieved by a focus across the individual, relationship, family, community, and societal-levels and across all sectors, private and public (e.g.,

**Comment [A]:** From LLD: The Crosby & Sacks reference is missing from the reference list. I looked it up online and noticed that the 13 million estimate is based on knowing a suicide decedent in the past year. Knowing someone who died by suicide seems potentially broader to me than being directly impacted.

**Comment [A]:** From TS: Has anyone updated this? It would be good to check.

**Comment [A]:** From TS: I don't think you need to start with "violence" and then focus on suicide.

**Comment [A]:** From LLD: they may also be impacted in other ways (e.g., loss of family income, etc.)

**Comment [A]:** From TS: It seems like it would be appropriate to acknowledge the CDC estimate too. Consider using that as a minimum and then say that others have estimated that the costs could be considerably higher after adjusting for under-reporting of suicide.

business, public health, physical and behavioral healthcare, justice, education, labor) (National Action Alliance for Suicide Prevention, 2014; World Health Organization, 2014).

### Assessing the Evidence

This technical package includes programs, practices, and policies with evidence of impact on suicide or risk or protective factors for suicide. To be considered for inclusion in the technical package, the program, practice, or policy selected had to meet at least one of these criteria: a) meta-analyses or systematic reviews showing impact on suicide; b) evidence from at least one rigorous (e.g., randomized controlled trial [RCT] or quasi-experimental design) evaluation study that found significant preventive effects on suicide; c) meta-analyses or systematic reviews showing impact on risk or protective factors for suicide, or d) evidence from at least one rigorous (e.g., RCT or quasi-experimental design) evaluation study that found significant impacts on risk or protective factors for suicide. Finally, consideration was also given to the likelihood of achieving beneficial effects on multiple forms of violence; no evidence of harmful effects on specific outcomes or with particular subgroups; and feasibility of implementation in a U.S. context if the program, policy, or practice has been evaluated in another country.

Within this technical package, some approaches do not yet have research evidence demonstrating impact on rates of suicide but instead are supported by evidence indicating impacts on risk or protective factors for suicide (e.g., help-seeking, stigma reduction, depression, connectedness). In terms of the strength of the evidence, programs that have demonstrated effects on suicidal behavior (e.g., reductions in deaths, attempts) provide a higher-level of evidence, but the evidence base is not that strong in all areas. For instance, there has been less evaluation of community engagement and family programs on suicidal behavior. Thus, approaches in this package that have effects on risk or protective factors reflect the **developmental** nature of the evidence base and the use of the best available evidence at a given time.

It is also important to note that there is often significant heterogeneity among the programs, policies, or practices that fall within one approach or strategy area in terms of the nature and quality of the available evidence. Not all programs, policies, or practices that utilize the same approach (e.g., gatekeeper training) are equally effective, and even those that are effective may not work across all populations. Tailoring programs and more evaluation may be necessary to address different population groups. The examples provided are not intended to be a comprehensive list of evidence-based programs, policies, or practices for each approach, but rather illustrate models that have been shown to impact suicide or have beneficial effects on risk or protective factors for suicide. In practice, the effectiveness of the programs, policies and practices identified in this package will be strongly dependent on the quality of their implementation and the communities in which they are implemented. Implementation guidance to assist practitioners, organizations and communities will be developed separately.

**Comment [A]:** From TS: “developmental nature” doesn’t seem correct. Do you mean the “current status”

## Context and Cross-Cutting Themes

The strategies and approaches that have been included in this technical package represent different levels of the social ecology, with efforts intended to impact the community and societal levels, as well individual and relationship levels. The strategies and approaches are intended to work in combination and reinforce each other to prevent suicide (see box below). The strategies are arranged in order such that those strategies hypothesized to have the greatest potential for broad public health impact on suicide are included first, followed by those that might impact more select populations (e.g., persons who have already made a suicide attempt).

Preventing Suicide	
Strategy	Approach
Strengthen economic supports	<ul style="list-style-type: none"><li>• Strengthen household financial security</li><li>• Housing stabilization policies</li></ul>
Strengthen access to mental health care	<ul style="list-style-type: none"><li>• Coverage of mental health conditions in health insurance policies</li></ul>
Create protective environments	<ul style="list-style-type: none"><li>• Reducing access to lethal means among persons at-risk of suicide</li><li>• Organizational policies and culture</li><li>• Community-based policies to reduce excessive alcohol use</li></ul>
Promote connectedness	<ul style="list-style-type: none"><li>• Peer norm approaches</li><li>• Community engagement activities</li></ul>
Teach coping and problem-solving skills	<ul style="list-style-type: none"><li>• Social-emotional learning</li><li>• Parenting skill and family relationship approaches</li></ul>
Identify and support people at risk	<ul style="list-style-type: none"><li>• Gatekeeper training</li><li>• Screening combined with care management</li><li>• Crisis intervention</li></ul>
Intervene to lessen harms and prevent future risk	<ul style="list-style-type: none"><li>• Treatment for people at-risk of suicide</li><li>• Treatment to prevent re-attempts</li><li>• Postvention</li><li>• Safe messaging following a suicide</li></ul>

The example programs, policies, and practices have been implemented within particular contexts. The social and cultural context of communities is critically important to take into account when selecting strategies and approaches. Practitioners in the field may be in the best position to assess the needs and strengths of their communities and work with community members to make decisions about the combination of approaches included here that are best suited to their context.

Suicide ideation, attempts, morbidity and mortality vary by gender, race/ethnicity, age, occupation, and other important population characteristics. Barriers to disclosure, help seeking, timely access to quality care, and ongoing support may also vary by population and community characteristics. Ideally, the availability of multiple approaches tailored to the economic, cultural, and environmental context of individuals and communities are desirable as they may increase the likelihood of removing barriers to supportive and effective care and provide opportunities to develop individual and community resilience. These culturally appropriate approaches can then be included in comprehensive strategies to maximize the public health impact on reducing suicide-related morbidity and mortality among individuals and within communities.

This package includes strategies where public health agencies are well positioned to bring leadership and resources to implementation efforts. It also includes strategies where public health can serve as an important collaborator (e.g., strategies addressing community and societal level risks), but where leadership and commitment from other sectors such as business, labor or health care is critical to implement a particular policy or program (e.g., workplace policies; screening combined with care management). The role of various sectors in the implementation of a strategy or approach in preventing suicide is described further in the section on *Sector Involvement*.

In the sections that follow, the strategies and approaches with the best available evidence for preventing suicide are described.

## Strengthen Economic Supports

### Rationale

Studies from the U.S. examining historical trends indicate that suicide rates increase during economic recessions marked by high unemployment rates, job losses, and economic instability and decrease during economic expansions and periods marked by low unemployment rates, particularly for working-age individuals 25 to 64 years old (Luo et al., 2011; Fowler et al., 2015). Economic and financial strain, such as job loss, long periods of unemployment, reduced income, difficulty covering medical, food, and housing expenses, and even the anticipation of such financial stress, can directly or indirectly increase an individual's risk for suicide; buffering these risks can therefore, potentially protect against suicide (Stack & Wasserman, 2007). For example, strengthening economic support systems can help people pay stay in their homes or obtain affordable housing while also paying for necessities such as food and medical care, job training, child care, among other expenses required for daily living. In providing this support, stress and anxiety and the potential for a crisis situation may be reduced, thereby preventing suicide.

### Approaches

Economic supports for individuals and families can be strengthened by targeting household financial security and ensuring stability in housing during periods of economic stress.

- **Strengthening household financial security** can potentially buffer the risk of suicide by providing individuals with the financial means to lessen the stress and hardship associated with a job loss or other unanticipated financial problems. The provision of unemployment benefits and other forms of temporary assistance, livable wages, medical benefits, and retirement and disability insurance to help cover the cost of necessities or to offset costs in the event of disability, are examples of ways to strengthen household financial security.
- **Housing stabilization policies** aim to keep people in their homes and provide housing options for those in need during times of financial insecurity. This may occur through programs that provide affordable housing such as through government subsidies or through other options available to potential homebuyers such as loan modification programs, move-out planning, or financial counseling services that help minimize the risk or impact of foreclosures and eviction.

### Potential Outcomes

- Reduced suicide rates
- Lower foreclosure rates
- Lower eviction rates
- Reduced emotional distress

**Comment [A]:** From TS: I was thinking that it might be good to work in a point about how these risks can be directly or indirectly associated with suicide risk because these stressors can exacerbate relationship as well physical and mental health problems.

**Comment [A]:** From TS: I like this clear and succinct summary.

**Comment [A]:** From JH: Consistent tense – reduced vs. reduce

**Comment [A]:** From LLD: the other packages use "Reductions in..."; you may want to consider using similar language for your potential outcomes.

## Evidence

There is evidence suggesting that strengthening household financial security and stabilizing housing can reduce suicide risk.

- **Strengthen household financial security.** An examination of variations in U.S. *unemployment benefit programs* across states demonstrated that the impact of unemployment on suicide was offset in those states that provided greater than average unemployment benefits (Cylus, Glymour, & Avendano, 2014). Another U.S. study examining the link between unemployment and suicide risk using monthly suicide data, length of unemployment, and job losses found that the duration of unemployment, as opposed to just the loss of job, predicted suicide risk (Classen & Dunn, 2012). Together, these results suggest that not only should state unemployment benefit programs be generous in their financial allocations, but also in their duration.

Other measures to strengthen household financial security (e.g., transfer payments related to retirement and disability insurance, unemployment insurance compensation, medical benefits, and other forms of family assistance) have also shown an impact on suicide. A study by Flavin and Radcliff (2009) examined the impact of states' per capita spending on transfer payments, medical benefits, and family assistance (Temporary Assistance to Needy Families – TANF) and total state spending on suicide rates between 1990-2000, controlling for a number of suicide risk factors (e.g., residential mobility, divorce rate, unemployment rate) at the state level. As per capita spending on total transfer payments, medical benefits, and family assistance increased there was an associated decrease in state suicide rates. Moreover, it wasn't spending in general that was associated with the reduction but spending on these types of assistance. In terms of lives saved, Flavin & Radcliff calculated the cost of reducing a state's suicide rate by a full point for the years studied. At the national level, they estimated that 3,000 fewer suicides would occur per year nationwide if every state increased their per capita spending on these types of assistance by \$45 per year (Flavin & Radcliff, 2009).

- **Housing stabilization policies.** The *National Neighborhood Stabilization Program* was designed to help neighborhoods suffering from high rates of foreclosure and abandonment by slowing the deterioration of the neighborhoods and providing affordable housing options for low, moderate, and middle-income homebuyers. This program also offers financial assistance to eligible individuals for the purchase of a new home. Although this program has not been rigorously evaluated for its impact on suicide outcomes, it addresses foreclosure and eviction, which are risk factors for suicide. A longitudinal analysis of annual data on suicides and foreclosures demonstrated that as the proportion of foreclosed properties increased in U.S. states, so did the state suicide rate, particularly among working-aged adults (Houle & Light, 2014). Another study

**Comment [A]:** From TS: Consider including a point about this being a correlational study and more evaluation work is needed but it suggests the potential benefits of policies that reach those who are particularly vulnerable at the times when they are in greatest need.

of data from 16 U.S. states participating in the National Violent Death Reporting System found that suicides precipitated by home foreclosures and evictions increased more than 100% from 2005 (before the housing crisis began) to 2010 (after it had peaked; Fowler, Gladden, Vagi, Barnes, and Frazier (2015)). Most of these suicides occurred prior to the actual loss of the decedent's home. These findings suggest that integrating suicide prevention resources, messaging, and referrals into financial, foreclosure, and move-out planning and counseling services may help to prevent suicide.

## Strengthen Access to Mental Health Care

### Rationale

While most people with mental health problems do not attempt or die by suicide (Olfson, Gerhard, Huang, Crystal, & Stroup, 2015; Owens, 2002), and risk conferred by mental illnesses differ (Arsenault-Lapierre, Kim, & Turecki, 2004; E. C. Harris & Barraclough, 1997; Tyrer, Reed, & Crawford, 2015), previous research indicates that mental illness is an important risk factor for suicide (E. C. Harris & Barraclough, 1998; World Health Organization, 2014). Studies suggest that up to 90% of people who die by suicide may have had a mental illness at the time of their deaths (Arsenault-Lapierre et al., 2004; Cavanagh, Carson, Sharpe, & Lawrie, 2003; Isometsa, 2001). State-level suicide rates have also been found to be correlated with general mental health measures such as depression (Lang, 2013; Mark, Shern, Bagalman, & Cao, 2007). Findings from the National Comorbidity Survey indicate that relatively few people in the U.S. with mental health disorders receive treatment for those conditions (Kessler et al., 2005). Lack of access to mental health care is one of the contributing factors related to the underuse of mental health services (Cunningham, 2009). Identifying ways to improve access to timely, affordable, and quality mental health care for people in need is a critical component to suicide prevention (World Health Organization, 2014). Apart from the treatment benefits, it can also serve to normalize help-seeking behavior and increase the use of such services.

### Approaches

One approach to strengthening access to mental health care is through the provision of mental health coverage in health insurance policies.

- **Coverage of mental health conditions in health insurance policies.** Federal and state laws include provisions for equal coverage of mental health services in health insurance plans that is on par with coverage for other health concerns (i.e., mental health parity). Benefits and services covered include such things as the number of visits, co-pays, deductibles, inpatient/outpatient services, prescription drugs, and hospitalizations. If a state has a stronger mental health parity law than the federal parity law, then insurance plans regulated by the state must follow the state parity law. Federal parity replaces the state law only in cases where the state law prevents the application of the federal parity law (e.g., includes coverage for some mental health conditions but not others). Equal coverage does not necessarily imply good coverage as health insurance plans vary in the extent to which benefits and services are offered to address various health conditions. Rather it helps to ensure that mental health services are covered on par with other health concerns.

### Potential Outcomes

- Increased utilization of mental health services

**Comment [A]:** From JM: I assume this means that different types of mental health problems pose different risks for suicide, but wasn't sure? May want to make the point more explicit

**Comment [A]:** From TS: Isn't this including substance abuse disorder? It would be good to state this explicitly.

**Comment [A]:** From TS: I found this sentence confusing. Can you reword to simplify this.

From LLD: could say: "if a state has a weaker parity law than the federal parity law (e.g., includes coverage for some mental health conditions but not others), then the federal parity law will replace the state law."

- Decreased symptoms of mental illnesses
- Decreased rates of suicide attempts
- Decreased rates of suicide

### Evidence

There is evidence suggesting that coverage of mental health conditions in health insurance policies can reduce risk factors associated with suicide and may directly impact suicide rates.

- **Coverage of mental health conditions in health insurance policies.** The National Survey of Drug Use and Health is a nationally representative survey of the U.S. population that provides data on substance use, mental health conditions, and services utilization. Using data from this survey, K. M. Harris, Carpenter, and Bao (2006) found that 12 months after states enacted *mental health parity laws*, self-reported use of mental healthcare services significantly increased. Moreover, subsequent research by Lang (2013) examined state mental health laws and suicide rates between 1990 and 2004 and found that mental health parity laws, specifically, were associated with an approximate 5% reduction in suicide rates. This reduction, in the 29 states with parity laws, equated to the prevention of 592 suicides per year and a cost savings of \$1.3-3.1 million per suicide prevented (Lang, 2013).

**Comment [A]:** From TS: I don't think this is accurate. I was curious about this study and checked out the paper. I think they are saying that this is the cost incurred per suicide prevented. They go on to explain that this is the upper bound and does not reflect the benefits to non-suicidal individuals. Please confirm this. If you are going to include this then it will be important to explain it further.

## Create Protective Environments

### Rationale

Prevention efforts that focus not only on individual behavior change (e.g., help-seeking, treatment interventions) but on changes to the environment can increase the likelihood of positive behavioral and health outcomes (Haddon, 1980). Creating environments that address risk and protective factors where individuals live, work, and play, can help prevent suicide (Dahlberg & Krug, 2002; U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012). For example, rates of suicide and suicide attempts are elevated in certain occupational groups (Han et al., 2016; McIntosh et al., 2016), therefore, changes to the organizational culture in these occupations, by way of implementation of supportive policies or even physical modifications to the workplace environment, can change social norms, encourage help-seeking, and demonstrate that good health and mental health are valued and that stigma and other risk factors for suicide are not (K. L. Knox et al., 2010; National Action Alliance for Suicide Prevention Workplace Task Force, 2015). Similarly, modifying the characteristics of the environment to prevent harmful behavior such as access to lethal means can reduce suicide rates, particularly in times of crisis (Beautrais, Gibb, Fergusson, Horwood, & Larkin, 2009; Crosby, Espitia-Hardeman, Ortega, & Lozano, 2013; Kaplan et al., 2013; Miller, Warren, Hemenway, & Azrael, 2015; C. W. Runyan et al., 2016).

### Approaches

The current evidence suggests three **promising** approaches for creating environments that protect against suicide.

- **Reducing access to lethal means among persons at-risk of suicide.** Means of suicide such as firearms, hanging/suffocation, or jumping from heights provide little opportunity for rescue and, as such, have high case fatality rates (e.g., about 85% of people who use a firearm in a suicide attempt will die from the injury). Research also indicates that 1) the interval between thinking about and attempting suicide can be as short as 5 or 10 minutes (Deisenhammer et al., 2009; Simon et al., 2001) and 2) that people tend *not* to substitute a different method when a highly lethal method is unavailable or difficult to access (Hawton, 2007; Yip et al., 2012). Therefore, increasing the time interval between the thought and the suicide attempt, for example, by making it more difficult to access lethal means, can be lifesaving. The following are examples of approaches reducing access to lethal means for persons at-risk of suicide:
  - *Intervening at Suicide Hotspots.* Suicide hotspots, or places where suicides may take place relatively easily, include tall structures (e.g., bridges and cliffs), railway tracks, and isolated locations such as parks. Efforts to prevent suicide at these locations include

**Comment [A]:** From JM: The word promising has certain connotations when using it around evidence. You say later that the evidence around this strategy is some of the strongest for suicide. These two statements seem somewhat inconsistent. I would use a different word here then promising if you truly believe there is strong evidence.

From JH: suggest deleting the word "promising"

From LLD: since we don't want to infer that these are the only approaches for creating protective environments, I might be inclined to change the word "promising" to "potential" or "possible" or something along those lines.

erecting barriers to prevent jumping and installing signs and telephones to encourage individuals who are considering suicide, to seek help (Cox et al., 2013).

- *Safe Storage Practices.* Safe storage of medications, firearms, and other household products can reduce the risk for suicide by separating individuals who may be vulnerable and/or impulsive from easy access to lethal means. Such practices may include education and counseling around storing firearms--locked in a secure place (e.g., in a gun safe or lock box), unloaded and separate from the ammunition--and keeping medicines in a locked cabinet or other secure location away from people who may be at risk or who have made prior attempts (Rowhani-Rahbar, Simonetti, & Rivara, 2016; C. W. Runyan et al., 2016).

- **Organizational policies and culture** that promote protective environments may be implemented in places of employment. Such policies and cultural values may promote prosocial behavior (e.g., asking for help), skill building, changing social norms, referral and access to helping services (e.g. mental health, substance abuse treatment, financial counseling), and encourage leadership support from the top down. Such policies and cultural shifts can positively impact organizational climate and morale and help prevent suicide and its related risk factors (e.g. depression, social isolation) (National Action Alliance for Suicide Prevention Workplace Task Force, 2015).
- **Community-based policies to reduce excessive alcohol use.** Research studies in the United States have found that greater alcohol availability is positively associated with alcohol-involved suicides (Escobedo & Ortiz, 2002; Giesbrecht et al., 2015). Policies to reduce excessive alcohol use broadly include zoning to limit alcohol outlet locations and density, taxes on alcohol, and bans on the sale of alcohol for individuals under the legal drinking age. These policies are important because acute alcohol use has been found to be associated with more than one-third of suicides and approximately 40% of suicide attempts (Cherpitel, Borges, & Wilcox, 2004).

#### Potential Outcomes

- Increase in safe storage of means
- Reduction in suicide attempts
- Reduction in suicide deaths
- Increase in help-seeking
- Reduction in alcohol-related suicide deaths

#### Evidence

The evidence for the effectiveness reducing access to lethal means for person at-risk of suicide and other ways to establish protective environments is some of the strongest in the field (Zalsman et al., 2016).

**Comment [A]:** From JM: Consistent with promising used earlier? Is it the strongest?

- **Reducing access to lethal means among persons at-risk of suicide.** A meta-analysis examining the impact of *suicide hotspot interventions* implemented in combination or in isolation, both in the U.S. and abroad, found associated reduced rates of suicide (Cox et al., 2013; Pirkis et al., 2015). For example, after erecting a barrier on the Jacques-Cartier bridge in Canada, the suicide rate from jumping from the bridge decreased from about 10 suicide deaths per year to about 3 deaths per year (Perron, Burrows, Fournier, Perron, & Ouellet, 2013). Moreover, the reduction in suicides by jumping was sustained even when all bridges and nearby jumping sites were considered, suggesting little to no displacement of suicides to other jumping sites (Perron et al., 2013). Further evidence for the effectiveness of bridge barriers was demonstrated by a study examining the impact of the *removal* of safety barriers from the Grafton Bridge in Auckland, New Zealand. After removal of the barrier, *sadly*, both the number and rate of suicide increased fivefold (Beautrais, 2001; Beautrais et al., 2009).

Another form of means reduction involves implementation of *safe storage practices*. In a case-control study of firearm-related events identified from 37 counties in Washington, Oregon, and Missouri, and from 5 trauma centers, Grossman et al. (2005) found that storing firearms unloaded, separate from ammunition, in a locked place or secured with a safety device was protective of suicide attempts among adolescents. Further, a recent systematic review of clinic and community-based education and counseling interventions suggested that the provision of safety devices significantly increased safe firearm storage practices compared to counseling alone or compared to the provision of economic incentives to acquire safety devices on one's own (Rowhani-Rahbar et al., 2016).

Another program, *The Emergency Department Counseling on Access to Lethal Means (ED CALM)*, trained psychiatric emergency clinicians in a large children's hospital to provide lethal means counseling and safe storage boxes to parents of patients under age 18 receiving care for suicidal behavior. In a pre-post quality improvement project, Runyan et al (2016) found that at post-test 76% (of the 55% of parents followed up, n=114) reported that all medications in the home were locked up as compared to fewer than 10% at the time of the initial emergency department visit. Among parents who indicated the presence of guns in the home at pre-test (i.e. 67%), all (100%) reported guns were currently locked up at post-test (C. W. Runyan et al., 2016).

- **Organizational policies and culture.** *Together for Life* is a workplace program of the Montreal Police Force implemented to address suicide among officers. Policy and program components were designed to foster an organizational culture that promoted mutual support and solidarity among all members of the Force. The program included training of supervisors, managers and all units to improve competencies in identifying suicidal risk and to improve use and awareness of existing resources. The program also included an education campaign to improve awareness and help-seeking (Mishara & Martin, 2012). Police suicides were tracked over 12 years and

compared to rates in the control city of Quebec. The suicide rate in the intervention group decreased significantly by 78.9% to a rate of 6.4 suicides per 100,000 population per year compared to an 11% increase in the control city (~~rate: 29.0~~ per 100,000) (Mishara & Martin, 2012).

Another example of this approach is the *United States Air Force Suicide Prevention Program (AFSPP)*. AFSPP included 11 policy and education initiatives and was designed to change the culture of the Air Force surrounding suicide. The program uses leaders as role models and agents of change, establishes expectations for behavior related to awareness of suicide risk, develops population skills and knowledge (i.e., education and training), and investigates every suicide (i.e., outcomes measurement). The program represents a fundamental shift from viewing suicide and mental illness solely as medical problem and instead sees them as larger service-wide problems impacting the whole community (K. L. Knox, Litts, Talcott, Feig, & Caine, 2003). Using a time-series design to examine the impact of the AFSPP program on various violence-related outcomes, researchers found that the program was associated with a 33% relative risk reduction in suicide (K. L. Knox et al., 2003). The program was also associated with relative risk reductions in related outcomes including moderate and severe family violence (30% and 54%, respectively), homicide (51%), and accidental death (18%) (K. L. Knox et al., 2003). A longitudinal assessment of the program over the period 1981 to 2008 (16 years before the 1997 launch of the program and 11 years post-launch) found significantly lower rates of suicide after the program was launched than before (K. L. Knox et al., 2010). These effects were sustained over time, except in 2004, which the authors found was associated with less rigorous implementation in that year than in the other years (K. L. Knox et al., 2010).

- **Community-based policies to reduce excessive alcohol use.** While multiple policies to limit excessive use of alcohol ~~use~~ exist, several studies on alcohol outlet *density*, specifically, suggest that measures to reduce alcohol outlet density can potentially reduce alcohol-involved suicides. Additionally, a longitudinal analysis of alcohol outlet density, suicide mortality, and hospitalizations for suicide attempts over 6 years in 581 California zip codes indicated that the density of bars, specifically, is related to suicide and suicide attempts, particularly in rural areas (Johnson, Gruenewald, & Remer, 2009).

## Promote Connectedness

### Rationale

Sociologist, Emile Durkheim theorized in 1897 that weak social bonds, i.e. lack of connectedness, are among the chief causes for suicidality (Durkheim, 1897/1951). *Connectedness* is the degree to which an individual or group of individuals are socially close, interrelated, or share resources with others (Centers for Disease Control and Prevention, 2009). Social connections can be formed within and between multiple levels of the social ecology (Dahlberg & Krug, 2002), for instance between individuals (e.g. peers, neighbors, co-workers), families, schools, neighborhoods, workplace, faith communities, cultural groups, and society as a whole. Related to connectedness, *social capital* refers to a sense of trust in one's community and neighborhood, social integration, and also the availability and participation in social organizations (Beyer, Layde, Hamberger, & Laud, 2015; Muennig, Cohen, Palmer, & Zhu, 2013). Many ecological cross-sectional and longitudinal studies have examined the impact of aspects of social capital on depression symptoms, depressive disorder, mental health more generally, and suicide. While the evidence is still being built the pattern is towards an inverse association between social capital measured by social trust, community/ neighborhood engagement, and improved mental health. Connectedness and social capital together can serve to protect against suicidal behaviors by decreasing isolation, encouraging adaptive coping behaviors, increasing belongingness, personal value and worth all of which helps individuals to build resilience in the face of adversity. Connectedness can also provide individuals with better access to formal supports and resources, mobilize communities to meet the needs of its members and provide collective primary prevention activities to the community as a whole (Centers for Disease Control and Prevention, 2009).

### Approaches

Promoting connectedness among individuals and within communities through modeling peer norms and enhancing community engagement can protect against suicide.

- **Peer norm approaches** seek to normalize prosocial behaviors/protective factors for suicide such as help-seeking, reaching out and talking to trusted adults, and peer connectedness. These approaches typically target youth and are delivered in school settings but can also be implemented in community settings.

**Comment [A]:** From JM: Seems like a nuance you can delete from this paragraph. You don't really pick up on this later and it probably requires more explanation

**Comment [A]:** From JH: Awkward wording. Consider, while the evidence is limited, existing studies suggest...

**Comment [A]:** From TS: I think you meant to say a "positive" association rather than "inverse".

**Comment [A]:** From JM: This implies that prosocial behavior is currently abnormal. Maybe promote is a better word?

From JH: suggest deleting "seek to normalize" and say "Peer norm approaches encourage prosocial behavior..."

- **Community engagement activities.** Community engagement is an aspect of social capital. Community engagement approaches may involve residents participating in a range of activities, including religious activities, community clean-up and greening activities, and physical exercise. These activities provide opportunities for residents to become more involved in the community and to connect with other community members, organizations, and resources, resulting in enhanced overall physical health, reduced stress, and decreased depressive symptoms, thereby reducing risk of suicide.

### Potential Outcomes

- Reduction in maladaptive coping attitudes and behaviors
- Increase in healthy coping attitudes and behaviors
- Increase in referrals for youth in distressed
- Increase help-seeking behaviors
- Positive perception of adult support

### Evidence

Current evidence suggests that peer norm approaches and community engagement can reduce risk factors associated with suicidal behaviors.

- **Peer norm approaches.** Evaluations show that programs such as *Sources of Strength* can improve school norms and beliefs about suicide that are created and disseminated by student peers. In a randomized controlled trial of *Sources of Strength* conducted with 18 high-schools (6 metropolitan, 12 rural), Wyman et al. (2010) found that the program improved peer leaders' adaptive norms regarding suicide, their connectedness to adults, and school engagement. Peer leaders were also more likely than controls to refer a suicidal friend to an adult. Among students, the intervention increased perceptions of adult support for suicidal youths and the acceptability of seeking help. Perception of adult support increased most in students with a history of suicidal ideation. Finally, trained peer leaders also reported a greater decrease in maladaptive coping attitudes compared with untrained leaders (Wyman et al., 2010).
- **Community engagement activities.** A vacant lot greening initiative was undertaken in Philadelphia between 1999 and 2008. Local residents and community members worked together to green 4,436 lots (or 7.8 million square feet) in 4 areas of the city. Researchers found significant associated reductions in community residents' self-reported stress levels and engagement in more physical exercise than residents in control vacant lot areas. Other benefits included reductions in firearm assaults and vandalism (Branas et al., 2011).

**Comment [A]:** From JH: Cite findings from Let's Connect intervention program? While the intervention didn't significantly reduce suicidal behavior, there were significant improvements in connectedness (a protective factor for suicide).

**Comment [A]:** From TS: Is there any evidence on outcomes more proximal to suicide? Did they look for any and not find them? It is important to describe relevant null effects when they were found.

**Comment [A]:** From JM: Not seeing strong evidence here. Are you suggesting that this affects documented risk factors for suicide by reducing stress and increasing physical exercise? I would like to see a stronger evidence statement here.

From LLD: you might want to incorporate a phrase in the statement along the lines of "which are risk factors for suicide"

**Comment [A]:** From TS: They had a follow up paper in 2013 that showed intervention sites felt significantly safer. The effects on crimes was encouraging but not significant. It seems important to mention this too.

From LLD: not sure I agree with Tom's last point about mentioning the nonsignificant effect on crime.

## Teach Coping and Problem-Solving Skills

### Rationale

Building life skills prepares individuals to successfully tackle every day challenges and adapt to stress and adversity. Life skills encompasses many concepts, but most often include coping and problem-solving skills, conflict resolution, and critical thinking. Life skills are important in shielding individuals from suicidal behaviors (World Health Organization, 2014). Suicide prevention programs that focus on life and social skills training are drawn from social cognitive theories (Bandura, 1986), surmising that **individuals** ~~(who) engage in~~ suicidal behavior is attributed to ~~(either)~~ direct learning, modeling, and environmental and individual (e.g. hopelessness) characteristics. The literature linking life skills and suicide is robust. The inability to employ adequate ~~cop~~ing strategies to cope with immediate stressors or identify and find solutions for problems ~~has~~ve been characterized among suicide attempters (Pollock & Williams, 2004). Treatments that include bolstering skills (Goldsmith, Pellmar, Kleinman, & Bunney, 2002) and include problem-solving techniques (Ghahramanlou-Holloway, Bhar, Brown, Olsen, & Beck, 2012; Townsend et al., 2001) appear to reduce suicidal ideation and attempts more effectively. Prevention programs focused on teaching these skills target youth, parents and families and have been used with both universal and at-risk populations. While many do not target suicidal behaviors directly, these programs strive to train youth and parents in important life skills to offset the underlying vulnerabilities that contribute to engaging in high-risk behaviors early in life.

Comment [A]: Specific edits needed here.

Comment [A]: From LLD: the word "either" here implies another comparative clause; should the word "or" be inserted before the word "modeling"? May want to just delete the word "either"

### Approaches

Current evidence provides support for the following two approaches:

- **Social emotional learning programs** focus on developing and strengthening communication and problem-solving skills, emotion regulation, conflict resolution, help seeking and coping skills. These approaches address a range of risk and protective factors for suicidal behavior. They provide children and youth with skills to resolve problems in relationships, school, and with peers, and help youth to address other negative influences (e.g., substance use) associated with suicide. These approaches are typically delivered to all students in a particular grade or school, although some programs also focus on groups of students considered to be at high risk for suicide. Opportunities to practice and reinforce skills are an important part of programs that work (Herman, Borden, Reinke, & Webster-Stratton, 2011).
- **Parenting skill and family relationship programs** are designed to strengthen parenting skills, enhance positive parent-child interactions, and improve children's behavioral and emotional skills and abilities. Several parenting and family relationship programs have been shown in rigorous evaluations to improve resilience and reduce risk factors for various behaviors, including

ones closely related to suicide, such as depression, internalizing behaviors, and substance abuse (M. S. Knox, Burkhart, & Hunter, 2010).

### Potential Outcomes

- Reduction in suicide attempts and suicide ideation
- Enhanced knowledge of risk and protective factors associated with suicide
- Reduction in suicide risk behaviors (i.e., depression, anxiety, conduct problems, substance abuse)
- Improve and normalize help-seeking behavior
- Enhance social competence and emotional regulation skills
- Enhance problem-solving and conflict management skills

### Evidence

There are several programs with evidence that support teaching social, emotional and parenting skills to reduce suicidal behaviors and associated risk factors.

- **Social emotional learning programs.** The *Youth Aware of Mental Health Program (YAM)* is a program developed for teenagers that uses interactive dialogue and role-playing to teach adolescents about the risk and protective factors associated with suicide (including knowledge about depression and anxiety) and enhances their problem-solving skills for dealing with adverse life events, stress, school and other problems. The program includes 3 hours of role-play sessions and interactive workshops combined with a booklet that students can keep, educational posters displayed in classroom, and interactive lectures about mental health at the beginning and end of the program (Wasserman et al., 2014). In a cluster-randomized controlled trial of YAM conducted across 10 European Union countries and 168 schools, students participating in the YAM program were significantly less likely to have an incident suicide attempt (OR 0.45, 95%CI 0.24–0.85;  $p=0.014$ ) and severe suicidal ideation (0.50, 0.27–0.92;  $p=0.025$ ) at the 12-month follow-up compared to the control group. Additionally, related to severe suicide ideation, in the YAM group absolute risk fell by 0.50% and relative risk fell by 49.6% (Wasserman et al., 2014).

*Signs of Suicide (SOS)* is another school-based prevention program for students aged 13–17. The program includes guided classroom discussions about suicide and depression. As part of the program, students are screened for depression and suicide risk and referred for professional help as indicated. The program is designed to increase knowledge about suicide and risk factors associated with suicidal behavior as well as improve and normalize help-seeking behavior (Schilling, Aseltine, & James, 2016). In a randomized controlled trial, SOS was shown to reduce self-reported suicide attempts at 3-months post intervention among

**Comment [A]:** From JH: Report ages (compare to SOS below)

**Comment [A]:** From JH: Suggest translating OR and 95% CI for wider audience.

From LLD: agree; this is too technical for a wider audience. See Tom's suggestion below.

**Comment [A]:** From JH: state if the control group received any kind of intervention

**Comment [A]:** From JH: significant?

**Comment [A]:** From TS: The Lancet paper has a 2015 publication date.

The authors provide the absolute and RR for suicide attempts too and they give a clear way of thinking about this – i.e., for RR “Of 1000 pupils, 11 attempted suicide in the control group vs five attempts in YAM”

It might be worth using the attempt example so you can provide this explanation.

**Comment [A]:** From JH: significant? Effect size/magnitude of reduction?

participating students compared to **control** students. The SOS program also **increased** students' knowledge of how to get help for themselves or friends for depression and/or suicidal thoughts, and favorable attitudes toward help-seeking. SOS participants with a lifetime history of suicide attempt were also less likely to report planning a suicide in the 3 months following the program compared to **lower-risk participants** (Schilling et al., 2016).

Finally, the *Good Behavior Game (GBG)* is a classroom-based program for elementary school children aged 6-10; **it represents an example of upstream suicide prevention programming**. The program uses a team-based behavior management strategy that promotes good behavior by setting clear expectations for good behavior and consequences for maladaptive behavior. The goal of the GBG is to create an integrated classroom social system that is supportive of all children being able to learn with little aggressive or disruptive behavior (Wilcox et al., 2008). **In an outcome evaluation of the GBG, first graders assigned to GBG reported half the adjusted odds of suicidal ideation and suicide attempts**. The beneficial effect of the program was consistent for suicidal ideation regardless of whether baseline covariates were included. The GBG effect on attempts was less robust in some adjusted models including caregiver mental health. In the **second cohort** of GBG students, neither suicidal ideation nor suicide attempts were significantly different between GBG and the control interventions (Wilcox et al., 2008). **This finding likely arose due to the lack of implementation fidelity** and pointed to the need for GBG to be delivered with precision, consistency, and teacher support. GBG was also found to be associated with reduced risk of later substance abuse, a risk factor for suicide (Kellam et al., 2008).

- **Parenting skill and family relationship programs.** Parenting and family skills training approaches have shown promising impacts in preventing key risk factors associated with suicide. For example, the *Incredible Years (IY)* is a comprehensive group training program for parents, teachers and children designed to reduce conduct and substance abuse problems, two important suicide risk factors, in youth by improving protective factors such as responsive and positive parent-teacher-child interactions and relationships, emotion self-regulation and social competence (all protective factors for suicide) (Herman et al., 2011). The program includes 9- 20 sessions offered in community-based settings (e.g., religious, recreation centers, mental health treatment centers, and hospitals). Several studies have demonstrated the effect of the IY program on reducing internalizing symptoms, such as anxiety and depression, and child conduct problems (C. H. Webster-Stratton, Reid, & Beauchaine, 2011; Webster-Stratton, Jamila Reid, & Stoolmiller, 2008). The program is also associated with improved problem-solving and conflict management; these skills were maintained at 1-year follow-up (Reid, Webster-Stratton, & Hammond, 2003; C. Webster-Stratton & Hammond,

**Comment [A]:** From JH: define control condition

**Comment [A]:** From JH: significant?

**Comment [A]:** From JH: Lower-risk? Do you mean students with no prior reported history of suicide attempts?

**Comment [A]:** From LLD: Jeff had questions about what is meant by upstream. You are referring to primary prevention but some of the other examples – YAM – are also primary prevention. Suggest just deleting this statement.

**Comment [A]:** From JH: compared to?

**Comment [A]:** From JH: Suggest stating clearly there are two separate cohorts of students receiving the intervention. How do these cohorts differ (time, location)?

**Comment [A]:** From TS: It is important to help the reader to understand that this study looked at the suicidal ideation when the first graders were age 19-21. This is not clear currently.

**Comment [A]:** From JH: Is this the authors' comment or your interpretation of the data? Please clarify.

1997; C. Webster-Stratton, Reid, & Hammond, 2001). The program demonstrated greater benefits as the dosage of the intervention increased (Herman et al., 2011).

Additionally, *Strengthening Families 10-14* is a program that involves sessions between parents, youth, and family with the goal of improving parents' skills for disciplining, managing emotions and conflict, and communicating with their children; promoting youths' interpersonal and problem-solving skills; and creating family activities to build cohesion and positive parent-child interactions. The premise of the program is that developing these skills for both parents and children will reduce internalizing behavior and adolescent substance abuse, two important risk factors for suicide (Spoth, Gyll, & Day, 2002). *Strengthening Families* has been shown to decrease externalizing behaviors, alcohol use, and drug use among youth participants and reductions in depression, alcohol use, and drug use among participating families (Spoth et al., 2002).

**Comment [A]:** From JH: significant? Also please define externalizing behaviors.

**Comment [A]:** From TS: This transition seems off.

## Identify and Support People At-Risk

### Rationale

In order to decrease suicide, attention to people at increased or high risk is necessary as these individuals tend to experience suicidal behavior at higher than average rates. These vulnerable or disadvantaged populations include, but are not limited to, individuals with lower socio-economic status or who are living with a mental health problem; people who have attempted suicide previously; individuals who are institutionalized, have been victims of violence, or are homeless; and members of certain racial and ethnic minority groups. Supporting these vulnerable groups requires proactive case finding along with access to, and retention in, mental health services. Finding effective ways of identifying at-risk or vulnerable groups, customizing services to make them accessible and maintaining engaged in care remain key challenges. For example, simply improving services does not guarantee that those services will be used by those most in need of them, nor will it necessarily increase the number of people who follow treatments that are recommended. People who are disadvantaged face social and economic issues that may adversely affect their ability to respond to the treatments or advice that are offered.

**Comment [A]:** From TS: This seems awkward as written. It might be better to say "...attention to people with specific vulnerabilities..."

### Approaches

The following three approaches focus on identifying and supporting people at increased risk.

- **Gatekeeper training** is designed to train teachers, coaches, providers and others in the community to identify people who may be at risk of suicide and to respond effectively, including facilitating treatment seeking and support services. Gatekeeper training is typically implemented in schools to identify at-risk youth and within health care settings to identify adults (and youth).
- **Screening combined with care management and overall continuity of care** has been used in primary care and behavioral health care settings to assure that people who may be at high-risk of suicide are identified and receive ongoing treatment as needed, particularly after inpatient discharge and other transitions within the healthcare system so they don't 'slip through the cracks'. These approaches typically employ screening for depression and/or suicide combined with collaborative treatment planning between patients and their providers and patient follow-up.
- **Crisis intervention.** These approaches provide support and referral services, typically by connecting a person in crisis (or a friend or family member of someone at-risk) to trained volunteers or professional staff via telephone hotline, online chat, or text messaging. Crisis intervention approaches are intended to impact key risk factors for suicide, including feelings of depression, hopelessness, and subsequent mental health care utilization. Like means reduction,

crisis interventions can put space or time between an individual who may be considering suicide and harmful behavior.

### Potential Outcomes

- Reduction in suicide attempts
- Reduction in suicide deaths
- Increased identification of individuals at-risk for suicidal behavior
- Increased at-risk individuals in treatment
- Increased community members trained to identify at-risk individuals
- Increased referrals for health care

### Evidence

There is evidence that community gatekeeper programs are successful in reducing suicides and suicide attempts but the efforts must be maintained (Substance Abuse and Mental Health Services Administration, 2014). However, there is limited evidence for effectiveness of screening programs, but at the same time, standard principles for public health screening make them promising (Pena & Caine, 2006). The number of studies evaluating crisis intervention services is limited, but a few studies do indicate that those who use the hotline services have decreased suicidal thoughts and behavior.

- **Gatekeeper training.** One example of gatekeeper training is the *Mental Health First Aid (MHFA)* program. This program is designed for the lay public and consists of three weekly sessions of three hours each. Participants learn the symptoms of people in mental health crises and/or in the early stages of mental health problems (i.e., those experiencing suicidal thoughts and behavior, acute stress reaction, panic attacks and acute psychotic behavior, and depression, anxiety, and psychotic disorders), possible risk factors, and where and how to get evidence-based effective help (Kitchener & Jorm, 2004). In a randomized controlled trial of 300 participants of MHFA, the intervention group reported significantly greater confidence in providing help to others, greater likelihood of advising people to seek professional help, improved concordance with health professionals about treatments, and decreased stigmatizing attitudes. Additionally, the intervention resulted in improved mental health of the participants themselves. All results were statistically significant at  $p < .05$ . (Kitchener & Jorm, 2004). Additional research rigorously evaluating MHFA for its impact on the first aid intervention recipients' themselves and suicidal behavior is needed (Kitchener & Jorm, 2006).

Gatekeeper training has also been a core part of all Garret Lee Smith (GLS) Suicide Prevention Program which is in place in 49 states and 48 tribes. A multi-site evaluation assessed the

**Comment [A]:** From LLD: suggest shortening this introductory statement about the evidence and making it consistent with the other sections. If you need to provide caveats, then you might want to take a look at the YV TP for example wording.

**Comment [A]:** From TS: Add cites here. Also this wording is awkward because it could be read as suggesting that those who chose to use the hotline are different from others at risk who did not. Maybe you could add the follow up period to the end – they have decrease suicidal thoughts and behavior at xx

**Comment [A]:** From LLD: wording is a bit awkward here

**Comment [A]:** From JH: compared to?

**Comment [A]:** From JH: significant? Is it possible to report magnitude of intervention effects?

**Comment [A]:** From JH: Overall mental health or specific facets (e.g., depression, etc.)? Please clarify

**Comment [A]:** From JH: Native American?

connection between community gatekeeper training and a reduction of suicide attempts and deaths by comparing the change in suicide mortality rates and nonfatal suicidal behavior among the population aged 10-24 in counties implementing *GLS* trainings, with the trajectory observed in similar counties that did not implement these trainings. Counties implementing *GLS* trainings had significantly lower youth suicide rates the year following the training implementation ( $-1.07$ ,  $p=.03$ ) (Walrath, Garraza, Reid, Goldston, & McKeon, 2015). This finding represents a decrease of 1 suicide death per 100,000 among youths 10 to 24 years of age or the avoidance of approximately 237 deaths in this age group between 2007 and 2010. Counties implementing *GLS* program activities also had significantly lower suicide attempt rates among youths 16 to 23 years of age in the year following implementation of the *GLS* program than did similar counties that did not implement *GLS* program activities (4.9 fewer attempts per 1000 youths [ $95\% \text{ CI}, 1.8-8.0$  fewer attempts per 1000 youths];  $p=.003$ ; (Godoy Garraza, Walrath, Goldston, Reid, & McKeon, 2015)). More than 79,000 suicide attempts may have been averted during the period studied following implementation of the *GLS* program.

- Screening combined with care management and overall continuity of care.** The Henry Ford Perfect Depression Care program was the pre-cursor to Zero Suicide, and its overall goal was to eliminate suicide. More broadly, though, the aim was to completely redesign depression care delivery to achieve breakthrough improvement in quality and safety by focusing on six aims: effectiveness, safety, patient centeredness, timeliness, efficiency, and equity among patients. The program developed concrete measures to assess progress on each of these aims and began with screening and assessment of each patient for suicide risk with coordinated continuous follow-up care system wide (C. E. Coffey, 2006). An examination of the impact of the Henry Ford Perfect Depression Care (Pre-cursor to Zero Suicide) program found that there was a dramatic and statistically significant decrease in the rate of suicide between the baseline years prior to the intervention (1999 and 2000) to the intervention years (2002-2009). During this time period, the suicide rate fell 82% (C. E. Coffey, 2006; C. E. Coffey, Coffey, & Ahmedani, 2013). Further, suicide rates also declined among HMO members who participated in targeted suicide prevention efforts and received mental health specialty services. However, for those HMO members who accessed only general medical services as opposed to specialty mental health services, the suicide rate increased (M. Coffey, Coffey, & Ahmedani, 2015).
- Crisis intervention.** Suicide prevention hotlines are one way to provide crisis intervention. In an evaluation of the effectiveness of the *National Suicide Prevention Lifeline (NSPL)* to prevent suicide, 1,085 suicidal individuals who called the hotline completed a standard risk assessment for suicide, and 380 of those completed a follow-up assessment between 1 and 52 days after the initial assessment. Researchers found that over half of the initial sample were seriously considering suicide when they called, and they had a plan for their suicide. Researchers also

**Comment [A]:** From JM: I think you need to provide a little more context on Henry Ford so the readers understands in what kind of population the reductions were experienced. I assume from the end that Henry Ford is some sort of HMO, but just a little more information would help clarify this description to readers.

**Comment [A]:** From JH: how much?

found that participants experienced significant decreases in suicidality over the course of the telephone session, and that levels of hopelessness and psychological pain continued to decrease after their initial call (Gould, Kalafat, Harrismunfakh, & Kleinman, 2007).

Comment [A]: From JH: Report magnitude of decrease?

Comment [A]: From JH: how long?

In another study, this time employing a randomized controlled trial, Gould, Cross, Pisani, Munfakh, and Kleinman (2013) assessed the impact of the *Applied Suicide Intervention Skills Training (ASIST)*, a widely implemented training program that helps hotline counselors, emergency workers, and other gatekeepers to identify and connect with suicidal individuals, understand their reasoning for living and dying, and assist with safely connecting those in need to available resources. The training was evaluated across the NSPL network of hotlines over the period 2008-2009. Using data from 1,410 suicidal individuals who called 17 Lifeline centers, researchers found that compared to callers who spoke to counselors that received the usual care training, individuals who spoke with counselors trained in *ASIST* were significantly more likely to feel less depressed, less suicidal, less overwhelmed, and more hopeful by the end of their call to the hotline. Counselors trained in *ASIST* were also more skilled at keeping callers on the phone longer and establishing a connection with them. However, training in *ASIST* did not result in more comprehensive suicide risk assessments than usual care training (Gould et al., 2013).

## Intervene to Lessen Harms and Prevent Future Risk

### Rationale

Individuals who have experienced mental health challenges, suicidal ideation, ~~and/or~~ who have made suicide attempts ~~and/or have~~ engaged in non-suicidal self-injury are at increased risk of suicide (U.S. Office of the Surgeon General & National Action Alliance for Suicide Prevention, 2012). Risk of suicide can also increase among those who have lost a friend, family member, co-worker, or other acquaintance to suicide (Pitman, Osborn, King, & Erlangsen, 2014). Exposure to sensationalized or uninformed reporting regarding on suicide may heighten the risk of suicide among vulnerable individuals and can inadvertently contribute to suicide contagion (Etzersdorfer & Sonneck, 1998; Niederkrotenthaler & Sonneck, 2007).

### Approaches

A broad array of approaches to lesson harms and reduce future risk of suicide among those at increased risk include the provision of mental health care and improved continuity of care, improving linkage to care through active post-discharge planning and follow-up that decreases barriers to ongoing therapeutic support, increasing connectedness to supportive others, addressing bereavement, and framing communications to emphasize resilience, decrease negative affect, and to prevent contagion.

- **Treatment for people at-risk of suicide** typically includes various forms of psychotherapy delivered by licensed providers to help individuals with mental health problems and other risk factors for suicide with problem-solving, impulsivity and emotion regulation.
- **Treatment to prevent re-attempts.** These approaches typically include follow-up contact and use diverse modalities (e.g., home visits, mail, telephone, e-mail) to engage recent suicide attempt survivors in continued treatment to prevent re-attempts. Treatment may focus on improved coping skills, mindfulness, and other emotional regulation skills, and may include case management home visits to increase adherence to treatment and continuity of care; and one-on-one interpersonal therapy and/or group therapy. Approaches that engage and connect attempters to peers and providers are especially important because many attempters do not present to aftercare; 12%-25% reattempt within a year, and 3%-9% of attempt survivors die by suicide within 1 to 5 years of their initial attempt (Inagaki et al., 2015)
- **Postvention** approaches are implemented *after* a suicide has taken place and may include debriefing sessions, counseling, and/or bereavement support groups for surviving friends and family members/loved ones. These programs have not typically been evaluated for their impact on suicide or suicidal behavior but may reduce survivors' guilt, feelings of depression, and complicated grief (Szumilas & Kutcher, 2011).

**Comment [A]:** From LLD: simplify statement and make it consistent with the other introductory statements about approaches. You may also want to take a look at the introductory statements to this section in the other TPs.

**Comment [A]:** From LLD: Suggest fleshing this description out a bit. You may want to mention how these are typically delivered (e.g., one on one or group formats; typical number of sessions, location, etc.).

- **Safe messaging following a suicide.** The manner in which information on a recent suicide is communicated to the public (e.g. school assemblies, mass media, social media) can heighten the risk of suicide among vulnerable individuals and can inadvertently contribute to suicide contagion. Therefore, responsible and safe reporting may help prevent suicide and suicide contagion.

**Comment [A]:** From JH: add something about contagion?

### Potential Outcomes

- Reduction in mental health-related sequelae
- Increase connectedness
- Improved coping skills
- Improved messaging following suicide
- Reduction in re-attempts

### Evidence

The evidence addressing strategies to lesson harm and prevent future risk of suicide includes the evaluation of effects of specific approaches on risk and protective factors as well as suicide-related mortality. However, because the evaluation of suicide-related mortality requires large sample sizes and extended follow-up, much of the evidence in this area primarily focuses on risk and protective factors.

- **Treatment for people at-risk of suicide.** There are a number of treatments with evidence of impact on risk and protective factors for suicide. One example is the *Improving Mood – Promoting Access to Collaborative Treatment (IMPACT)* program. *IMPACT* aims to prevent suicide among older primary care patients by reducing suicide ideation and depression in primary care settings. It facilitates the development of a therapeutic alliance, a personalized treatment plan that includes patient preferences, as well as proactive follow-up (biweekly during an acute phase and monthly during continuation phase) by a depression care manager (Hunkeler et al., 2006). The program has been shown to significantly improve quality of life, and to reduce functional impairment, depression and suicidal ideation over 24-months of follow-up (Hunkeler et al., 2006; Unutzer et al., 2006) relative to patients who received care as usual.

Another example is *Collaborative Assessment and Management of Suicidality (CAMS)*, which is a therapeutic approach for suicide-specific assessment and treatment of patient's suicide risk. This flexible approach can be used across treatment settings and clinician theoretical orientations and involves the clinician and patient working together in an interactive assessment process to develop patient-specific treatment plans. *CAMS* sessions are collaborative and involve constant

patient about what is and is not working with the ultimate goal of enhancing the therapeutic alliance and increasing treatment motivation in the suicidal patient. CAMS been tested and supported in 6 correlational studies (Jobes, 2012), in a variety of inpatient and outpatient settings and in one RCT with several additional RCTs under way. CAMS has been associated with significant improvements in suicidal ideation, overall symptom distress, and feelings of hopelessness at 12 month follow-up among a community-based sample of suicidal outpatients. (Comtois et al., 2011).

Other examples include *Dialectical Behavioral Therapy (DBT)* and *Attachment-Based Family Therapy (ABFT)*. DBT is a multicomponent therapy for individuals at high risk for suicide and who may struggle with impulsivity and emotional regulation. The components of DBT include individual therapy, group skills training, between-session telephone coaching and a therapist consultation team. In a randomized controlled trial of women with recent suicidal or self-injurious behavior, those receiving DBT were half as likely to make a suicide attempt at two-year follow-up than women receiving community treatment (23% vs 46%), required less hospitalization for suicide ideation, and had lower medical risk across all suicide attempts and self-injurious acts combined (Linehan et al., 2006).

ABFT is a program for adolescents aged 12-18 and is designed to treat clinically diagnosed major depressive disorder, eliminate suicidal ideation, and reduce dispositional anxiety (Diamond et al., 2010). A randomized controlled trial of ABFT found that suicidal adolescents assigned to ABFT experienced significantly greater improvement in suicidal ideation over 24 weeks of follow-up than did adolescents assigned to enhanced usual care. Additionally, a significantly higher percentage of ABFT participants reported no suicidal ideation in the week prior to assessment at 12 weeks than did adolescents receiving enhanced usual care (69.2% vs. 34.6%;  $p = .01$ ;  $OR = 4.25$ ) and at 24 weeks (82.1% vs. 46.2%;  $p = .006$ ;  $OR = 5.37$ ) (Diamond et al., 2010).

- **Treatment to prevent re-attempts.** Several strategies that aim to prevent re-attempts have demonstrated impact on reducing suicidal behavior. For example, *Emergency Department Brief Intervention with Follow-up Visits* is a program that involves a one-hour discharge information session that addresses suicidal behavior, distress, risk and protective factors, alternatives to suicidal behavior, and referral options, combined with nine follow-up contacts over 18 months (at 1, 2, 4, 7, 11 weeks and 4, 6, 12, 18 months). Follow-up contacts are either conducted by phone or through home visits according to a specific time line for up to 18-months. A randomized controlled trial that enrolled suicide attempters from eight hospital emergency departments in five culturally different sites found that a brief intervention combined with 9 follow-up visits over 18-months was associated with significantly fewer deaths from suicide relative to a treatment-as-usual group (0.2% versus 2.2%, respectively;  $chi^2 = 13.83$ ,  $P < 0.001$ ) (Fleischmann et al., 2008).

Comment [A]: From TS: I think a word is missing – "patient input"?

Comment [A]: From JH: Unclear. According to the article, this program was evaluated in five countries. Please state the countries. Thnx.

Another example of treatment to prevent re-attempts involves *active follow-up contact approaches* such as postcards, letters, and telephone calls, ~~are~~ intended to increase a patient's sense of connectedness with health care providers and decrease isolation. These approaches include expression of care and support and typically invite patients to reconnect with their provider. Contacts are made periodically (e.g., monthly or every few months in the first 12 months post-discharge with some programs continuing contact for two or more years). In a meta-analysis conducted by Inagaki et al. (2015), interventions to prevent repeat suicidal behavior in patients admitted to an emergency department for suicide attempt were ~~These approaches have been found - in a meta-analysis conducted by Inagaki et al. (2015)~~ to reduce reattempts by approximately 17% for up to 12 months post-discharge; however, the long-term effects of these approaches on reattempts has not yet been demonstrated. Also, because the number of trials and associated sample sizes included in this meta-analysis were small, it was not possible to determine the effect of active contact and follow-up approaches on death by suicide. In a randomized controlled trial of the post-crisis suicide prevention long-term follow-up contact approach, Motto and Bostrom (2001) found that patients who refused ongoing care but who were randomized to be contacted by letter four times per year had a lower rate of suicide over two years of follow-up than did patients in the control group who received no further contact. Other studies have also shown post-crisis letters and coping cards to be protective against suicide ideation and attempts (Hassanian-Moghaddam, Sarjami, Kolahi, & Carter, 2011; Wang et al., 2016).

Finally, *Cognitive Behavior Therapy for Suicide Prevention (CBT-SP)* is an example of a therapeutic approach to prevent re-attempts. It uses a risk-reduction, relapse prevention approach that includes an analysis of proximal risk factors and stressors (e.g., relationship problems, school or work-related difficulties) leading up to and following the suicidal event; safety plan development; skill building; and psychoeducation. *CBT-SP* also has family skill modules focused on family support and communication patterns as well as improving the family's problem solving skills. A randomized controlled trial ~~found~~ of *CBT-SP* found that 10-session outpatient cognitive therapy designed to prevent repeat suicide attempts resulted in a 50% reduction in the likelihood of a suicide reattempt among adults who had been admitted to an emergency department for a suicide attempt relative to treatment as usual (Brown et al., 2005).

- **Postvention** programs are implemented with the goal of providing support to survivors of others' suicide to reduce their own risk of suicide. One example of a postvention program, *StandBy Response Service (StandBy)*, provides clients with face-to-face outreach and telephone support through a professional crisis response team. Site coordinators develop customized case management plans, referring clients to other existing community services matched to their needs

Comment [A]: From JH: Define (follow-ups greater than 1 year)

Comment [A]: From JH: Define

Comment [A]: From TS: "found" is repeated

(Visser, Comans, & Scuffham, 2014). In a study by Visser et al. (2014), *StandBy* clients were significantly less likely to be at high risk for suicidality than a suicide bereaved comparison group who had not had contact with the *StandBy* program (48% and 64% respectively). Additionally, research suggests that active postvention approaches in which outreach to suicide survivors occurs at the scene of a suicide is associated with intake into treatment sooner, greater attendance at support group meetings, and attendance at more meetings compared to passive postvention (versus passive approaches where survivors self-refer for services) (J. Cerel & Campbell, 2008).

- **Safe messaging following a suicide.** Safe messaging after a suicide can help assure that reporting of the event is done in such a way to reduce risk to consumers of news media and other messaging who may be particularly vulnerable. One way to ensure safe messaging following a suicide is to encourage that reporters adhere to *media guidelines for reporting on suicides*. Reports that are both inclusive of suicide prevention messages, stories of hope and resilience, risk and protective factors, and links to helping resources (e.g., hotline) and that avoid sensationalizing events or reducing suicide to one cause can help reduce the likelihood of suicide contagion. The most compelling evidence supporting the effect of *media guidelines* on reduction in suicides comes from Austria. After a sharp increase in suicides on the Viennese subway, media guidelines were introduced and an interrupted time series design was used to evaluate the national impact of the guidelines on subsequent suicides. Changes in the quality and quantity of media reporting resulted in a significant reduction of 81 suicides (annually) (95% confidence interval: -149 to -13; t = -2.32, df = 54, p < 0.024) in the (Viennese subway) system (Niederkrotenthaler & Sonneck, 2007).

**Comment [A]:** From TS: Don't you mean "Recommendations for Reporting on Suicide"? Please cite: <http://afsp.org/wp-content/uploads/2016/01/recommendations.pdf>

The media did not want "guidelines" and they reacted negatively to the idea of external guidelines.

**Comment [A]:** From TS: Are you sure that the 81 reduction was just on the subway system? I thought that was nationally. Please confirm.

**Comment [A]:** From JH: other evaluations available?

**Comment [A]:** From TS: Thomas also had a 2010 report that suggested benefits of good reporting. <http://bjp.rcpsych.org/content/bjprcpsych/197/3/234.full.pdf>

## Sector Involvement

Public health can play an important and unique role in addressing suicide. Public health agencies, which typically place prevention at the forefront of efforts and work to create broad population-level impact, can bring critical leadership and resources to bear on this problem. For example, these agencies can serve as a convener, bringing together partners and stakeholders to plan, prioritize, and coordinate suicide prevention efforts. Public health agencies are also well positioned to collect and disseminate data, implement preventive measures, evaluate programs, and track progress. Although public health can play a leadership role in preventing suicide, the strategies and approaches outlined in this technical package cannot be accomplished by the public health sector alone. As noted in the National Strategy to Prevent Suicide, the integration and coordination of prevention activities across sectors and settings is critical for expanding the reach and impact of suicide prevention efforts.

Other sectors vital to implementing this package include, but are not limited to, education, government (local, state, and federal), social services, health services, business, labor, justice, housing, media, and organizations that comprise the civil society sector such as faith-based organizations, youth-serving organizations, foundations, and other non-governmental organizations. Collectively, these sectors can make a difference in preventing suicide by impacting the various contexts and underlying risks that contribute to suicide.

The strategies and approaches described in this technical package are summarized in Appendix A along with the relevant sectors that are well positioned to lead implementation efforts. For example, business and labor, health care insurers and providers, and government entities are in the best position to implement programs and policies that *Strengthen Economic Supports and Access to Mental Health Care*. These types of supports go beyond individual behavior change and require commitment and support from those sectors that can directly address some of the underlying risks and the environmental contexts that increase the risk for suicide. Public health entities can play an important role by gathering and synthesizing information to inform policy, raise awareness, and evaluate the effectiveness of various policies. Moreover, partnerships with non-governmental and community organizations can be instrumental in increasing awareness of and garnering support for policies affecting individuals and families.

The public health sector has been at the forefront of many community-based prevention efforts, working collaboratively with schools and community-based organizations, to change social norms and positively impact health behavior. Public health is well suited to take on a similar leadership role in *Promoting Connectedness* through peer norm and community engagement activities and supporting the development, evaluation, and adoption of effective programs that *Teach Coping and Problem-Solving Skills* to prevent suicide from happening in the first place. These programs are often delivered in school and community settings, making education and non-governmental organizations vital partners in prevention.

Businesses, workplaces, and local and state government entities, on the other hand, are in the best position to establish policies and support practices that *Create Protective Environments* where people live, work, and play. Public health entities can play an important role by gathering and synthesizing information, working with other agencies within the executive branch of their state or local government in support of policy and other approaches, and evaluating the effectiveness of measures taken. In a similar fashion, public health entities can partner with schools, workplaces, and community organizations to implement and evaluate prevention programs, policies and practices geared toward creating safe, healthy, and supportive environments.

Finally, this technical package includes a number of interventions delivered in hospital, primary care, behavioral health care, and community settings designed to *Identify and Support People At-Risk* and to *Lessen Harms and Prevent Future Risk*. The intensity and activities of these interventions require the expertise of professionals who are licensed and trained to deliver critical intervention support. The health care, social services, and justice sectors can work collaboratively to support individuals at high-risk for suicide and their families. These activities also require coordination of supports across various service providers and community organizations.

Regardless of strategy, action by many sectors will be necessary for the successful implementation of this package. In this regard, all sectors can play an important and influential role in preventing suicide from happening in the first place and lessening the immediate and long-term harms of suicidal behavior by helping those in times of crisis get the services and support they need.

## Monitoring and Evaluation

Monitoring and evaluation are necessary components of the public health approach to prevention. It is important to have timely and reliable data to monitor the extent of the problem and to evaluate the impact of prevention efforts. Data are necessary for program implementation as planning, implementation, and assessment all rely on accurate measurement of the problem.

Surveillance data helps researchers and practitioners track changes in the burden of suicide. Surveillance systems exist at the federal, state, and local levels. It is important to assess the availability of surveillance data and data systems across these levels to identify and address gaps in the systems. CDC's National Vital Statistics System and the National Violent Death Reporting System (NVDRS) are examples of surveillance systems that provide data on deaths from suicide. NVDRS, for example, is a state-based surveillance system that combines data from death certificates, law enforcement reports, and coroner or medical examiner reports to provide detailed information on the circumstances of violent deaths, including suicide, which can assist communities in guiding prevention approaches (Blair, Fowler, Jack, & Crosby, 2016). The National Electronic Injury Surveillance System-All Injury Program (NEISS-AIP) provides nationally representative data about all types and causes of nonfatal injuries treated in U.S. hospital emergency departments, and can be used to assess national rates of, and trends in, self-harm injuries by cause (e.g., falls, poisoning, etc.), age, race/ethnicity, sex, disposition (where the injured person goes when released from the Emergency Department).

In addition to information on deaths and nonfatal injuries, there are also surveillance systems that provide national, state, and some local estimates of suicidal behavior. The Youth Risk Behavior Surveillance System (YRBSS) collects information from a nationally representative sample of 9-12 grade students and is a key resource in monitoring health-risk behaviors among youth, including whether youth have seriously considered attempting suicide, attempted suicide, made a plan, or required treatment by a doctor or nurse for a suicide attempt that resulted in an injury, poisoning, or overdose (Brener et al., 2013). The YRBSS data are obtained from a national school-based survey conducted by CDC as well as from state, territorial, tribal, and large urban school district surveys conducted by education and health agencies. The National Survey on Drug Use and Health (NSDUH) is an annual nationwide survey of individuals aged 12 years and older that provides national and state-level estimates of drug use and mental health-related issues, including suicide ideation and suicide attempts.

It is also important at all levels (local, state, and federal) to address gaps in responses, track progress of prevention efforts and evaluate the impact of those efforts, including the impact of this technical package. Evaluation data, produced through program implementation and monitoring, is essential to provide information on what does and does not work to reduce rates of suicide and its associated risk and protective factors. Theories of change and logic models that identify short, intermediate, and long-term outcomes are an important part of program evaluation.

**Comment [A]:** From TS: This description seems incomplete compared to the description of YRBS

The evidence-base for suicide prevention has advanced greatly over the last few decades. However, additional research is needed to understand the impact of prevention programs on preventing suicide, as opposed to merely examining the effectiveness of programs to impact risk factors associated with suicide. More research is also needed to examine the effectiveness of upstream and community-level strategies to prevent suicide at the population level. Lastly, it will be important for researchers to test the effectiveness of combinations of the strategies and approaches included in this package. Most existing evaluations focus on approaches implemented in isolation. However, but there is potential to understand the synergistic effects within a comprehensive prevention approach. Additional research is needed to understand the extent to which combinations of strategies and approaches result in greater reductions in suicide than individual programs, practices, or policies.

Comment [A]: From TS: Should this be programs, policies, and practices to be consistent?

Comment [A]: From JH: including attempts?

Comment [A]: From JH: great point!

Comment [A]: From JH: redundant with prior sentence.

Comment [A]: From TS: I found this somewhat awkward. The idea of suicide struggling seemed off and the point is not entirely clear. I think you can be more specific and reference an earlier point in the media recommendations section.

Comment [A]: From JH: Upstream/downstream is jargon.

Comment [A]: From TS: I think you can drop this and just use the more descriptive text. You don't need both. You could describe this as a range.

## Conclusion

Suicide is a serious public health problem whose rates have been on the rise for more than a decade and whose costs stretch well into the billions of dollars each year. And while suicide is a rare outcome statistically, its human impact has a ripple effect that is far-reaching. Each of us likely interacts with suicide survivors, those with lived experience, and those with thoughts of suicide, on a daily basis—at home, at work, and in our communities. Suicide and suicide attempts are therefore public health issues of societal concern. Fortunately, like many public health problems, suicide is preventable, and fortunately more is being done to prevent suicide than ever before, as evidenced by the work of the National Action Alliance for Suicide Prevention, the release of the first world report on suicide, and more timely surveillance data, to name just a few examples. Unfortunately and unlike most other public health problems, suicide still struggles against stigma, shame, and secrecy related to help-seeking, mental illness, being a survivor, or someone with lived experience; misplaced fear of asking someone about their risk of suicide (versus the fear and consequence of not asking), and fear of taking up certain strategies known to be effective but perhaps unpopular; misinformation about suicide preventability, and disproportionate funding given the public health burden. Suicide also struggles against the right degree of awareness where too much information, for example by well-meaning reporters and others, may actually do harm.

In an effort to continue pushing the field and society further towards prevention, this technical package includes strategies and approaches that ideally would be used in a comprehensive fashion, in combination—in a multi-level, multi-sectoral way. This technical package includes strategies and approaches targeting upstream prevention (e.g., social emotional learning for children and youth), as well as strategies focused more downstream (e.g., cognitive behavioral treatment to prevent re-attempts). It includes universal, selective, and indicated strategies, or strategies that focus on the whole population regardless of risk to strategies that focus on those groups at highest risk. Importantly, this technical package extends the bounds of the typical prevention strategies to consider approaches at the

(outer levels of the social ecology), e.g., policies to stabilize housing and community engagement initiatives. ~~In short, care and attention has been paid to all aspects of suicide prevention~~

While the evidence base continues to ~~be built~~emerge, the collection of programs, policies, and practices laid out here are available for implementation now. And in keeping with good public health practice, the intent is that monitoring and evaluation will play a key role in that implementation. Moreover, as new evidence becomes available, this technical package can be refined to reflect the current state of the science.

In closing, and in keeping with a message of resilience as spoken by those with lived experience, 'hope, help, and healing is possible.'

**Comment [A]:** From JM: Yes this is jargon, so the e.g., helps, but you might want to figure out a way to say this without referring to the outer levels of the social ecology.

**Comment [A]:** This sets you up for people to say oh yeah what about... AI/AN, transgendered people, prisoners etc.

## Appendix A: Summary of Strategies and Approaches to Prevent Suicide

Strategy	Approach/Program, Practice or Policy	Best Available Evidence			Lead Sectors <sup>1</sup>
		Suicide	Suicide Attempts or Ideation	Other Risk/Protective Factors for Suicide	
Strengthen economic supports	<b>Strengthen household financial security</b>				Government (local, state, Federal)
	<i>Unemployment benefit programs</i>	✓			
	<i>Other income supports</i>	✓			Business/labor
	<b>Housing stabilization policies</b>				Government (local, state, Federal)
	<i>The National Neighborhood Stabilization Program</i>			✓	
Strengthen access to mental health care	<b>Coverage of mental health conditions in health insurance policies</b>				Health care
	<i>Mental Health Parity Laws</i>	✓		✓	Government (state, Federal)
Establish protective environments	<b>Reducing access to lethal means among persons at-risk</b>				Government (local, state)
	<i>Intervening at suicide hot spots</i>	✓			
	<i>Safe storage practices</i>		✓	✓	Public Health
	<b>Organizational policies and culture</b>				Business/Labor
	<i>Together for Life</i>	✓			
	<i>US Air Force Suicide Prevention Program</i>	✓		✓	Government (local, state, Federal)

		Best Available Evidence			
	<b>Community-based policies to reduce excessive alcohol use</b>				Government (local, state)
	<i>Alcohol outlet density</i>	✓		✓	Business/labor
<b>Promote connectedness</b>	<b>Peer norm approaches</b>				Public Health
	<i>Sources of Strength</i>			✓	Education
	<b>Community-engagement activities</b>				Public Health
	<i>Greening vacant urban spaces</i>			✓	Government (local)
<b>Teach coping and problem-solving skills</b>	<b>Social emotional learning</b>				Public Health
	<i>Youth Aware of Mental Health Program</i>		✓		Education
	<i>Signs of Suicide</i>		✓	✓	
	<i>Good Behavior Game</i>		✓	✓	
	<b>Parenting skill and family relationship approaches</b>				Public Health
	<i>The Incredible Years</i>			✓	Education
	<i>Strengthening Families 10-14</i>			✓	
<b>Identify and</b>	<b>Gatekeeper training</b>				Public Health
	<i>Mental Health First Aid</i>			✓	Healthcare
	<b>Screening combined with care management</b>				Healthcare

		Best Available Evidence			
support people at-risk	<i>Henry Ford Perfect Depression Care (Pre-cursor to Zero Suicide)</i>	✓		✓	Social Services
	<b>Crisis Intervention</b>				Public Health
	<i>National Suicide Prevention Lifeline</i>		✓	✓	Social Services
	<i>Applied Suicide Intervention Skills Training</i>		✓	✓	
Intervene to lessen harms and prevent future risk	<b>Treatment for people at risk of suicide</b>				Healthcare
	<i>Improving Mood – Promoting Access to Collaborative Treatment (IMPACT)</i>		✓	✓	Social Services Justice
	<i>Collaborative Assessment and Management of Suicidality (CAMS)</i>		✓	✓	
	<i>Dialectical Behavioral Therapy</i>		✓	✓	
	<i>Attachment-Based Family Therapy</i>		✓		
	<b>Treatment to prevent re-attempts</b>				Healthcare
	<i>ED Brief Intervention with Follow-up Visits</i>	✓			Social Services
	<i>Active follow-up contact approaches</i>	✓	✓		
	<i>CBT for Suicide Prevention</i>				
	<b>Postvention</b>				Healthcare

		Best Available Evidence			
	<i>StandBy Response Service</i>		✓		
	<b>Safe messaging following a suicide</b>				Public Health
	<i>Media Guidelines</i>	✓			Media

<sup>1</sup>This column refers to the lead sectors well positioned to bring leadership and resources to implementation efforts. For each strategy, there are many other sectors such as non-governmental organizations that are instrumental to prevention planning and implementing the specific programmatic activities.

## Acknowledgements

We would like to thank the following individuals who contributed in specific ways to the development of this technical package. We give special thanks to Linda Dahlberg for her vision, guidance, and support throughout the development of this package. We thank Division, Center, and CDC leadership for their careful review and helpful feedback on earlier iterations of this document. We thank Alida Knuth for her formatting and design expertise. Last but definitely not least, we extend our thanks and gratitude to all the external reviewers for their helpful feedback, support and encouragement for this resource.

## Overview

This technical package represents a select group of strategies based on the best available evidence to help communities and states sharpen their focus on prevention activities with the greatest potential to prevent suicide. These strategies include: strengthening economic supports; strengthening access and delivery of suicide care; creating protective environments; promoting connectedness; teaching coping and problem-solving skills; identifying and supporting people at-risk; and lessening harms and preventing future risk. The strategies represented in this package include those with a focus on preventing suicide from happening in the first place as well as approaches to lessen the immediate and long-term harms of suicidal behavior for individuals, families, communities, and society. The strategies in the technical package support the goals and objectives of the *National Strategy for Suicide Prevention*<sup>1</sup> and the National Action Alliance for Suicide Prevention's priority to strengthen community-based prevention.<sup>2</sup> Commitment, cooperation, and leadership from numerous sectors, including public health, education, justice, health care, social services, business, labor, and government can bring about the successful implementation of this package.

### What is a Technical Package?

A technical package is a compilation of a core set of strategies to achieve and sustain substantial reductions in a specific risk factor or outcome.<sup>3</sup> Technical packages help communities and states prioritize prevention activities based on the best available evidence. This technical package has three components. The first component is the **strategy** or the preventive direction or actions to achieve the goal of preventing suicide. The second component is the **approach**. The approach includes the specific ways to advance the strategy. This can be accomplished through *programs, policies, and practices*. The **evidence** for each of the approaches in preventing suicide or its associated risk factors is included as the third component. This package is intended as a resource to guide and inform prevention decision-making in communities and states.

### Preventing Suicide is a Priority

Suicide, as defined by the Centers for Disease Control and Prevention (CDC), is part of a broader class of behavior called *self-directed violence*. Self-directed violence refers to behavior directed at oneself that deliberately results in injury or the *potential* for injury.<sup>4</sup> Self-directed violence may be *suicidal* or *non-suicidal* in nature. For the purposes of this document, we refer only to behavior where suicide is intended:

- **Suicide** is a death caused by self-directed injurious behavior with any intent to die as a result of the behavior.
- **Suicide attempt** is defined as a *non-fatal* self-directed and potentially injurious behavior with any intent to die as a result of the behavior. A suicide attempt may or may not result in injury.

**Suicide is highly prevalent.** Suicide presents a major challenge to public health in the United States and worldwide. It contributes to premature death, morbidity, lost productivity, and health care costs.<sup>1,5</sup> In 2015 (the most recent year of available death data), suicide was responsible for 44,193 deaths in the U.S., which is approximately one suicide every 12 minutes.<sup>6</sup> In 2015, suicide ranked as the 10th leading cause of death and has been among the top 12 leading causes of death since 1975 in the U.S.<sup>7</sup> Overall suicide rates increased 28% from 2000 to 2015.<sup>6</sup> Suicide is a problem throughout the life span; it is the third leading cause of death for youth 10-14 years of age, the second leading cause of death among people 15–24 and 25-34 years of age; the fourth leading cause among people 35 to 44 years of age, the fifth leading cause among people ages 45-54 and eighth leading cause among people 55-64 years of age.<sup>6</sup>

Suicide rates vary by race/ethnicity, age, and other population characteristics, with the highest rates across the lifespan occurring among non-Hispanic American Indian/Alaska Native (AI/AN) and non-Hispanic White population groups. In 2015, the rates for these groups were 19.9 and 16.9 per 100,000 population, respectively.<sup>6</sup> Other population groups disproportionately impacted by suicide include middle-aged adults (whose rates increased 35% from 2000 to 2015, with steep increases seen among both males (29%) and females (53%) aged 35-64 years<sup>6</sup>; Veterans and other military personnel (whose suicide rate nearly doubled from 2003 to 2008, surpassing the rate of suicide among civilians for the first time in decades)<sup>8,9</sup>; workers in certain occupational groups,<sup>10,11</sup> and sexual minority youth, who experience increased suicidal ideation and behavior compared to their non-sexual minority peers.<sup>12-14</sup>

Suicides reflect only a portion of the problem.<sup>15</sup> Substantially more people are hospitalized as a result of nonfatal suicidal behavior (i.e. suicide attempts) than are fatally injured, and an even greater number are either treated in ambulatory settings (e.g., emergency departments) or not treated at all.<sup>15</sup> For example, during 2014, among adults aged 18 years and older, for every one suicide there were 9 adults treated in hospital emergency departments for self-harm injuries, 27 who reported making a suicide attempt, and over 227 who reported seriously considering suicide.<sup>6,16</sup>

**Suicide is associated with several risk and protective factors.** Suicide, like other human behaviors, has no single determining cause. Instead, suicide occurs in response to multiple biological, psychological, interpersonal, environmental and societal influences that interact with one another, often over time.<sup>1,5</sup> The social ecological model – encompassing multiple levels of focus from the individual, relationship, community, and societal – is a useful framework for viewing and understanding suicide risk and

protective factors identified in the literature.<sup>17</sup> Risk and protective factors for suicide exist at each level. For example, risk factors include:

- **Individual level:** history of depression and other mental illnesses, hopelessness, substance abuse, certain health conditions, previous suicide attempt, violence victimization and perpetration, and genetic and biological determinants
- **Relationship level:** high conflict or violent relationships, sense of isolation and lack of social support, family/loved one's history of suicide, financial and work stress
- **Community level:** inadequate community connectedness, barriers to health care (e.g., lack of access to providers and medications)
- **Societal level:** availability of lethal means of suicide, unsafe media portrayals of suicide, stigma associated with help-seeking and mental illness.<sup>1,5</sup>

It is important to recognize that the vast majority of individuals who are depressed, attempt suicide, or have other risk factors, do *not* die by suicide.<sup>18,19</sup> Furthermore, the relevance of each risk factor can vary by age, race, gender, sexual orientation, residential geography, and socio-cultural and economic status.<sup>1,5</sup>

Protective factors, or those influences that buffer against the risk for suicide, can also be found across the different levels of the social ecological model. Protective factors identified in the literature include: effective coping and problem solving skills, moral objections to suicide, strong and supportive relationships with partners, friends, and family; connectedness to school, community, and other social institutions; availability of quality and ongoing physical and mental health care, and reduced access to lethal means.<sup>1,5</sup> These protective factors can either counter a specific risk factor or buffer against a number of risks associated with suicide.

**Suicide is connected to other forms of violence.** Exposure to violence (e.g., child abuse and neglect, bullying, peer violence, dating violence, sexual violence, and intimate partner violence) is associated with increased risk of depression, post-traumatic stress disorder (PTSD), anxiety, suicide, and suicide attempts.<sup>20-26</sup> Women exposed to partner violence are nearly 5 times more likely to attempt suicide as women not exposed to partner violence.<sup>26</sup> Exposure to adverse experiences in childhood, such as physical, sexual, emotional abuse and neglect, and living in homes with violence, mental health, substance abuse problems and other instability, is also associated with increased risk for suicide and suicide attempts.<sup>22,27</sup> The psychosocial effects of violence in childhood and adolescence can be observed decades later, including severe problems with finances, family, jobs, and stress – factors that can increase the risk for suicide. Suicide and other forms of violence often share the same individual, relationship, community, and societal risk factors suggesting that efforts to prevent interpersonal violence may also prove beneficial in preventing suicide.<sup>28-30</sup> Further, just as risk factors may be shared across suicide and interpersonal violence, so too may protective factors overlap. For example,

connectedness to one's community,<sup>31</sup> school,<sup>32</sup> family,<sup>33</sup> caring adults,<sup>34,35</sup> and pro-social peers<sup>36</sup> can enhance resilience and help reduce risk for suicide and other forms of violence.

**The health and economic consequences of suicide are substantial.** Suicide and suicide attempts have far reaching consequences for individuals, families, and communities.<sup>37-40</sup> In an early study, Crosby and Sacks<sup>41</sup> estimated that 7% of the U.S. adult population, or 13.2 million adults, knew someone in the prior 12 months who had died by suicide. They also estimated that for each suicide, 425 adults were exposed, or knew about the death.<sup>41</sup> In a more recent study, in one state, Cerel et al<sup>42</sup> found that 48% of the population knew at least one person who died by suicide in their lifetime. Research indicates that the impact of knowing someone who died by suicide and/or having lived experience (i.e., personally have attempted suicide, have had suicidal thoughts, or have been impacted by suicidal loss) is much more extensive than injury and death. People with lived experience may suffer long-term health and mental health consequences ranging from anger, guilt, and physical impairment, depending on the means and severity of the attempt.<sup>43</sup> Similarly, survivors of a loved one's suicide may experience ongoing pain and suffering including complicated grief,<sup>44</sup> stigma, depression, anxiety, post-traumatic stress disorder, and increased risk of suicidal ideation and suicide.<sup>45,46</sup> Less discussed but no less important, are the financial and occupational effects on those left behind.<sup>47</sup>

The economic toll of suicide on society is immense as well. According to conservative estimates, in 2013, suicide cost \$50.8 billion in estimated lifetime medical and work-loss costs alone.<sup>47</sup> Adjusting for potential under-reporting of suicide and drawing upon health expenditures per capita, gross domestic product per capita, and variability among states in per capita health care expenditures and income, another study estimated the total lifetime costs associated with nonfatal injuries and deaths caused by self-directed violence to be approximately \$93.5 billion in 2013.<sup>48</sup> The overwhelming burden of these costs were from lost productivity over the life course, with the average cost per suicide being over \$1.3 million.<sup>48</sup> The true economic costs are likely higher, as neither study included monetary figures related to other societal costs such as those associated with the pain and suffering of family members or other impacts.

**Suicide can be prevented.** Like most public health problems, suicide is preventable.<sup>1,5</sup> While progress will continue to be made into the future, evidence for numerous programs, practices, and policies currently exists, and many programs are ready to be implemented now. Just as suicide is not caused by a single factor, research suggests that reductions in suicide will not be prevented by any single strategy or approach.<sup>1,49</sup> Rather, suicide prevention is best achieved by a focus across the individual, relationship, family, community, and societal-levels and across all sectors, private and public.<sup>1,5</sup>

## Assessing the Evidence

This technical package includes programs, practices, and policies with evidence of impact on suicide or risk or protective factors for suicide. To be considered for inclusion in the technical package, the program, practice, or policy selected had to meet at least one of these criteria: a) meta-analyses or systematic reviews showing impact on suicide; b) evidence from at least one rigorous (e.g., randomized controlled trial [RCT] or quasi-experimental design) evaluation study that found significant preventive effects on suicide; c) meta-analyses or systematic reviews showing impact on risk or protective factors for suicide, or d) evidence from at least one rigorous (e.g., RCT or quasi-experimental design) evaluation study that found significant impacts on risk or protective factors for suicide. Finally, consideration was also given to the likelihood of achieving beneficial effects on multiple forms of violence; no evidence of harmful effects on specific outcomes or with particular subgroups; and feasibility of implementation in a U.S. context if the program, policy, or practice has been evaluated in another country.

Within this technical package, some approaches do not yet have research evidence demonstrating impact on rates of suicide but instead are supported by evidence indicating impacts on risk or protective factors for suicide (e.g., help-seeking, stigma reduction, depression, connectedness). In terms of the strength of the evidence, programs that have demonstrated effects on suicidal behavior (e.g., reductions in deaths, attempts) provide a higher-level of evidence, but the evidence base is not that strong in all areas. For instance, there has been less evaluation of community engagement and family programs on suicidal behavior. Thus, approaches in this package that have effects on risk or protective factors reflect the developing nature of the evidence base and the use of the best available evidence at a given time.

It is also important to note that there is often significant heterogeneity among the programs, policies, or practices that fall within one approach or strategy in terms of the nature and quality of the available evidence. Not all programs, policies, or practices that utilize the same approach are equally effective, and even those that are effective may not work across all populations. Tailoring programs and conducting more evaluations may be necessary to address different population groups. The evidence-based programs, practices, or policies included in the package are not intended to be a comprehensive list for each approach, but rather to serve as examples that have been shown to impact suicide or have beneficial effects on risk or protective factors for suicide.

### **Context and Cross-Cutting Themes**

One important feature of the package is the complementary and potentially synergistic impact of the strategies and approaches. The strategies and approaches included in this technical package represent different levels of the social ecology, with efforts intended to impact community and societal levels, as well individual and relationship levels. The strategies and approaches are intended to work in combination and reinforce each other to prevent suicide (see box below). The strategies are arranged in order such that those strategies hypothesized to have the greatest potential for broad public health impact on suicide are included first, followed by those that might impact subsets of the population (e.g., persons who have already made a suicide attempt).

Preventing Suicide	
Strategy	Approach
Strengthen economic supports	<ul style="list-style-type: none"> <li>• Strengthen household financial security</li> <li>• Housing stabilization policies</li> </ul>
Strengthen access and delivery of suicide care	<ul style="list-style-type: none"> <li>• Coverage of mental health conditions in health insurance policies</li> <li>• Reduce provider shortages in underserved areas</li> <li>• Safer suicide care through systems change</li> </ul>
Create protective environments	<ul style="list-style-type: none"> <li>• Reduce access to lethal means among persons at-risk of suicide</li> <li>• Organizational policies and culture</li> <li>• Community-based policies to reduce excessive alcohol use</li> </ul>
Promote connectedness	<ul style="list-style-type: none"> <li>• Peer norm programs</li> <li>• Community engagement activities</li> </ul>
Teach coping and problem-solving skills	<ul style="list-style-type: none"> <li>• Social-emotional learning programs</li> <li>• Parenting skill and family relationship programs</li> </ul>
Identify and support people at-risk	<ul style="list-style-type: none"> <li>• Gatekeeper training</li> <li>• Crisis Intervention</li> <li>• Treatment for people at-risk of suicide</li> <li>• Treatment to prevent re-attempts</li> </ul>
Lessen harms and prevent future risk	<ul style="list-style-type: none"> <li>• Postvention</li> <li>• Safe reporting and messaging about suicide</li> </ul>

It is important to note that these strategies are not mutually exclusive but each has an immediate focus. For instance, social-emotional learning programs, an approach under the *Teach Coping and Problem-Solving Skills* strategy, sometimes include components to change peer norms and the broader environment. The primary focus of these programs, however, is to provide children and youth with skills to resolve problems in relationships, school, and with peers, and to help youth address other negative influences (e.g., substance use) associated with suicide.

The goal of this package is to stress the importance of comprehensive prevention efforts and to provide examples of effective programs addressing each level of the social ecology, with the knowledge that some programs, practices, and policies may impact multiple levels. Further, those that involve multiple sectors and that impact multiple levels of the social ecology are more likely to have a greater impact on the overall burden of suicide.

Suicide ideation, thoughts, attempts, and deaths vary by gender, race/ethnicity, age, occupation, and other important population characteristics.<sup>6,50</sup> Further, certain transition periods are also associated

with higher rates of suicide (e.g., transition from working into retirement, transition from active duty military status to civilian status).<sup>48,51</sup> In fact, suicide risk can change along with dynamic risk factors. For example, individuals' coping skills may change during periods of crisis and heightened stress, limiting their normal ability to effectively solve problems and cope. Research indicates that suicide risk changes as a result of the number and intensity of key risk and protective factors experienced.<sup>52</sup> Ideally, the availability of multiple strategies and approaches tailored to the social, economic, cultural, and environmental context of individuals and communities are desirable as they may increase the likelihood of removing barriers to supportive and effective care and provide opportunities to develop individual and community resilience.<sup>1</sup>

Identifying programs, practices, and policies with evidence of impact on suicide, suicide attempts, or beneficial effects on risk or protective factors for suicide is only the first step. In practice, the effectiveness of the programs, policies and practices identified in this package will be strongly dependent on how well programs are implemented, as well as the partners and communities in which they are implemented. Practitioners in the field may be in the best position to assess the needs and strengths of their communities and work with community members to make decisions about the combination of approaches included here that are best suited to their context.

Data-driven strategic planning processes can help communities with this work.<sup>53-55</sup> These planning processes engage and guide community stakeholders through a prevention planning process designed to address a community's profile of risk and protective factors with evidence-based programs, practices, and policies. These processes can also be used to monitor implementation, track outcomes, and make adjustments as indicated by the data. The readiness of the program for broad dissemination and implementation (e.g., availability of program materials, training and technical assistance) can also influence program effects. Implementation guidance to assist practitioners, organizations and communities will be developed separately.

This package includes strategies where public health agencies are well positioned to bring leadership and resources to implementation efforts. It also includes strategies where public health can serve as an important collaborator (e.g., strategies addressing community and societal level risks), but where leadership and commitment from other sectors such as business, labor or health care is critical to implement a particular policy or program (e.g., workplace policies; treatment to prevent re-attempts). The role of various sectors in the implementation of a strategy or approach in preventing suicide is described further in the section on *Sector Involvement*.

In the sections that follow, the strategies and approaches with the best available evidence for preventing suicide are described.

## Strengthen Economic Supports

### Rationale

Studies from the U.S. examining historical trends indicate that suicide rates increase during economic recessions marked by high unemployment rates, job losses, and economic instability and decrease during economic expansions and periods marked by low unemployment rates, particularly for working-age individuals 25 to 64 years old.<sup>56,57</sup> Economic and financial strain, such as job loss, long periods of unemployment, reduced income, difficulty covering medical, food, and housing expenses, and even the anticipation of such financial stress may increase an individual's risk for suicide or may indirectly increase risk by exacerbating related physical and mental health problems.<sup>58</sup> Buffering these risks can, therefore, potentially protect against suicide. For example, strengthening economic support systems can help people stay in their homes or obtain affordable housing while also paying for necessities such as food and medical care, job training, child care, among other expenses required for daily living. In providing this support, stress and anxiety and the potential for a crisis situation may be reduced, thereby preventing suicide. Although more research is needed to understand how economic factors interact with other factors to increase suicide risk, the available evidence suggests that strengthening economic supports may be one opportunity to buffer suicide risk.

### Approaches

Economic supports for individuals and families can be strengthened by targeting household financial security and ensuring stability in housing during periods of economic stress.

- **Strengthening household financial security** can potentially buffer the risk of suicide by providing individuals with the financial means to lessen the stress and hardship associated with a job loss or other unanticipated financial problems. The provision of unemployment benefits and other forms of temporary assistance, livable wages, medical benefits, and retirement and disability insurance to help cover the cost of necessities or to offset costs in the event of disability, are examples of ways to strengthen household financial security.
- **Housing stabilization policies** aim to keep people in their homes and provide housing options for those in need during times of financial insecurity. This may occur through programs that provide affordable housing such as through government subsidies or through other options available to potential homebuyers such as loan modification programs, move-out planning, or financial counseling services that help minimize the risk or impact of foreclosures and eviction.

### Potential Outcomes

- Reductions in foreclosure rates

- Reductions in eviction rates
- Reductions in emotional distress
- Reductions in rates of suicide

## Evidence

There is evidence suggesting that strengthening household financial security and stabilizing housing can reduce suicide risk.

- **Strengthen household financial security.** The *Federal-State Unemployment Insurance Program* allows states to define the maximum amount and duration of unemployment benefits that workers are entitled to receive after a job loss.<sup>59</sup> An examination of variations in *unemployment benefit programs* across states demonstrated that the impact of unemployment on rates of suicide was offset in those states that provided greater than average unemployment benefits (mean level: \$7,990 per person in U.S. constant dollars). The effects of *unemployment benefit programs* were also consistent by sex and age group.<sup>59</sup> Another U.S. study examining the link between unemployment and suicide rates using monthly suicide data, length of unemployment (less than 5 weeks, 5-14 weeks, 15-26 weeks, and greater than 26 weeks), and job losses found that the duration of unemployment, as opposed to just the loss of job, predicted suicide risk.<sup>60</sup> Together, these results suggest that not only should state unemployment benefit programs be generous in their financial allocations, but also in their duration.

Other measures to strengthen household financial security (e.g., transfer payments related to retirement and disability insurance, unemployment insurance compensation, medical benefits, and other forms of family assistance) have also shown an impact on rates of suicide. A study by Flavin and Radcliff<sup>61</sup> examined the impact of states' per capita spending on transfer payments, medical benefits, and family assistance (Temporary Assistance to Needy Families – TANF) and total state spending on suicide rates between 1990-2000, controlling for a number of suicide risk factors (e.g., residential mobility, divorce rate, unemployment rate) at the state level. As per capita spending on total transfer payments, medical benefits, and family assistance increased there was an associated decrease in state suicide rates. In terms of lives saved, Flavin and Radcliff calculated the cost of reducing a state's suicide rate by a full point for the years studied.<sup>61</sup> At the national level, they estimated 3,000 fewer suicides would occur per year nationwide if every state increased its per capita spending on these types of assistance by \$45 per year.<sup>61</sup> Although this was a correlational study, the results demonstrate the potential benefits of policies that reach particularly vulnerable individuals during periods of great need. More evaluation studies are needed to further understand the outcomes impacted by programs such as these.

- **Housing stabilization policies.** The *Neighborhood Stabilization Program*<sup>62</sup> was designed to help neighborhoods suffering from high rates of foreclosure and abandonment by slowing the deterioration of the neighborhoods and providing affordable housing options for low, moderate, and middle-income homebuyers. This program also offers financial assistance to eligible individuals for the purchase of a new home. Although this program has not been rigorously evaluated for its impact on suicide outcomes, it addresses foreclosure and eviction, which are risk factors for suicide. A longitudinal analysis of annual data on suicides and foreclosures demonstrated that as the proportion of foreclosed properties increased in U.S. states, so did the state suicide rate, particularly among working-aged adults.<sup>63</sup> Another study of data from 16 U.S. states participating in the *National Violent Death Reporting System* found that suicides precipitated by home foreclosures and evictions increased more than 100% from 2005 (before the housing crisis began) to 2010 (after it had peaked).<sup>57</sup> Most of these suicides occurred prior to the actual loss of the decedent's home. These findings suggest that integrating suicide prevention resources, messaging, and referrals into financial, foreclosure, and move-out planning and counseling services may help to prevent suicide.

## Strengthen Access and Delivery of Suicide Care

### Rationale

While most people with mental health problems do not attempt or die by suicide<sup>18,19</sup> and the level of risk conferred by different types of mental illness varies,<sup>64-66</sup> previous research indicates that mental illness is an important risk factor for suicide.<sup>5,67</sup> State-level suicide rates have also been found to be correlated with general mental health measures such as depression.<sup>68,69</sup> Findings from the *National Comorbidity Survey* indicate that relatively few people in the U.S. with mental health disorders receive treatment for those conditions.<sup>70</sup> Lack of access to mental health care is one of the contributing factors related to the underuse of mental health services.<sup>71</sup> Identifying ways to improve access to timely, affordable, and quality mental health and suicide care for people in need is a critical component to prevention.<sup>5</sup> Additionally, research suggests that services provided are maximized when health and behavioral health care systems are set up to effectively and efficiently deliver such care.<sup>72</sup> Apart from treatment benefits, these approaches can also normalize help-seeking behavior and increase the use of such services.

### Approaches

There are a number of approaches that can be used to strengthen access and delivery of suicide care, including:

- **Coverage of mental health conditions in health insurance policies.** Federal and state laws include provisions for equal coverage of mental health services in health insurance plans that is on par with coverage for other health concerns (i.e., mental health parity).<sup>73</sup> Benefits and services covered include such things as the number of visits, co-pays, deductibles, inpatient/outpatient services, prescription drugs, and hospitalizations. If a state has a stronger mental health parity law than the federal parity law, then insurance plans regulated by the state must follow the state parity law. If a state has a weaker parity law than the federal parity law (e.g., includes coverage for some mental health conditions but not others), then the federal parity law will replace the state law. Equal coverage does not necessarily imply good coverage as health insurance plans vary in the extent to which benefits and services are offered to address various health conditions. Rather it helps to ensure that mental health services are covered on par with other health concerns.
- **Reduce provider shortages in underserved areas.** Access to effective and state-of-the-art mental health care is largely dependent upon the training and the size of the mental health care workforce. Over 85 million Americans live in areas with an insufficient number of mental health providers; this shortage is particularly severe among low-income urban and rural communities.<sup>74</sup> There are various ways to increase the number and distribution of practicing mental health providers in underserved areas including offering financial incentives through existing state and

federal programs (e.g., loan repayment programs) and expanding the reach of health services through telephone, video and web-based technologies. Such approaches can increase the likelihood that those in need will be able to access affordable, quality care for mental health problems, which can reduce risk for suicide.

- **Safer suicide care through systems change.** Access to health and behavioral health care services is critical for people at risk of suicide; however this is just one piece of the puzzle. Care should also be delivered efficiently and effectively. More specifically, care should take place within a system that supports suicide prevention and patient safety through strong leadership, workforce training, systematic identification and assessment of suicide risk, implementation of evidence-based treatments (see *Identify and Support People At-Risk*), continuity of care, and continuous quality improvement. Care that is patient-centered and promotes equity for all patients is also of critical importance.<sup>75</sup>

### Potential Outcomes

- Increased use of mental health services
- Lower rates of treatment attrition
- Reductions in depressive symptoms
- Reductions in rates of suicide attempts
- Reductions in rates of suicide

### Evidence

There is evidence suggesting that coverage of mental health conditions in health insurance policies and improving access and the delivery of care can reduce risk factors associated with suicide and may directly impact suicide rates.

- **Coverage of mental health conditions in health insurance policies.** The *National Survey on Drug Use and Health (NSDUH)* is a nationally representative survey of the U.S. population that provides data on substance use, mental health conditions, and service utilization.<sup>50</sup> Using data from this survey, Harris, Carpenter, and Bao<sup>76</sup> found that 12 months after states enacted *mental health parity laws*, self-reported use of mental healthcare services significantly increased. Moreover, subsequent research by Lang<sup>69</sup> examined state mental health laws and suicide rates between 1990 and 2004 and found that mental health parity laws, specifically, were associated with an approximate 5% reduction in suicide rates. This reduction, in the 29 states with parity laws, equated to the prevention of 592 suicides per year.<sup>69</sup>
- **Reduce provider shortages in underserved areas.** One example of a program to improve access to mental health care providers is the *National Health Service Corps (NHSC)*, which offers

financial incentives to attract mental/behavioral health clinicians to underserved areas.<sup>77</sup> Programs such as *NHSC* encourage individuals to work in the mental health profession in locations designated as Health Professional Shortage Areas (HPSAs) in exchange for student loan debt repayment. A 2012 retention survey conducted by the Health Resources and Services Administration (HRSA), found that 61% of mental and behavioral health care providers continued to practice in designated mental health shortage areas after their four year commitment to the *NHSC*.<sup>78</sup> Although this program has not been evaluated for impact on suicide, it addresses access to care, which is a critical component to suicide prevention.

*Telemental Health (TMH)* services refer to the use of telephone, video and web-based technologies for providing psychiatric or psychological care at a distance.<sup>79</sup> *TMH* can be used in a variety of settings (e.g. outpatient clinics, hospitals, military treatment facilities) to treat a wide range of mental health conditions. It can also improve access to care for patients in isolated areas, as well as reduce travel time and expenses, reduce delays in receiving care, and improve satisfaction interacting with the mental health care system. A systematic review of *TMH* services found that services rated as high or good quality were effective in treating mental health conditions such as depression, schizophrenia, substance abuse, and suicidal ideation and suicide.<sup>79</sup> Further, Mohr and colleagues<sup>80</sup> conducted a meta-analysis examining the effect of psychotherapy delivered specifically via telephone and found that it significantly reduced depressive symptoms in comparison to face-to-face psychotherapy. They also found that treatment attrition rates were significantly lower among patients receiving telephone-administered psychotherapy compared to patients receiving face-to-face therapy.<sup>80</sup> Thus, *TMH* may not only offer improved access to mental health care, but it may also ensure continuity of care, and thereby further reduce the risk for suicide.

- **Safer suicide care through systems change.** *Henry Ford Health System*, which is a large health maintenance organization (HMO) in the state of Michigan, pioneered *Perfect Depression Care*,<sup>81</sup> the pre-cursor to what is now called *Zero Suicide*. The overall goal of *Perfect Depression Care* was to eliminate suicide among HMO members. More broadly, the goal of the program was to redesign delivery of depression care to achieve “breakthrough improvement” in quality and safety by focusing on effectiveness, safety, patient centeredness, timeliness, efficiency, and equity among patients. The program screened and assessed each patient for suicide risk and implemented coordinated continuous follow-up care system wide.<sup>81</sup> An examination of the impact of the program found that there was a dramatic and statistically significant decrease in the rate of suicide between the baseline years, 1999 and 2000, prior to the intervention to the intervention years, 2002-2009. During this time period, the suicide rate fell by 82%.<sup>81,82</sup> Further, among HMO members who received mental health specialty services, the suicide rate significantly decreased over time from 1999 to 2010 (110.3 to 47.6 per 100,000 population;  $p < .04$ ) with a mean of 36.2 per 100,000 over the period. Additionally, for those HMO members

who accessed only general medical services as opposed to specialty mental health services, the suicide rate increased from 2.7 to 5.6 per 100,000 ( $p < .01$ ).<sup>82</sup> Similarly, in the state of Michigan, rates of suicide in the general population increased over the period from 9.8 to 12.5 per 100,000 ( $p < .001$ ).<sup>83</sup>

FINAL

## Create Protective Environments

### Rationale

Prevention efforts that focus not only on individual behavior change (e.g., help-seeking, treatment interventions) but on changes to the environment can increase the likelihood of positive behavioral and health outcomes.<sup>84</sup> Creating environments that address risk and protective factors where individuals live, work, and play can help prevent suicide.<sup>1,17</sup> For example, rates of suicide are high among middle-aged adults who comprise 42.6% of the workforce<sup>85</sup>; among certain occupational groups<sup>10,11</sup>; and among people in detention facilities (e.g. jail, prison),<sup>86</sup> to name a few. Thus, settings where these populations work and reside are ideal for implementing programs, practices and policies to buffer against suicide. Changes to organizational culture through the implementation of supportive policies, for instance, can change social norms, encourage help-seeking, and demonstrate that good health and mental health are valued and that stigma and other risk factors for suicide are not.<sup>87,88</sup> Similarly, modifying the characteristics of the physical environment to prevent harmful behavior such as access to lethal means can reduce suicide rates, particularly in times of crisis or transition.<sup>89-94</sup>

### Approaches

The current evidence suggests three potential approaches for creating environments that protect against suicide.

- **Reduce access to lethal means among persons at-risk of suicide.** Means of suicide such as firearms, hanging/suffocation, or jumping from heights provide little opportunity for rescue and, as such, have high case fatality rates (e.g., about 85% of people who use a firearm in a suicide attempt will die from the injury).<sup>95</sup> Research also indicates that: 1) the interval between deciding to act and attempting suicide can be as short as 5 or 10 minutes,<sup>96,97</sup> and 2) people tend *not* to substitute a different method when a highly lethal method is unavailable or difficult to access.<sup>98,99</sup> Therefore, increasing the time interval between deciding to act and the suicide attempt, for example, by making it more difficult to access lethal means, can be lifesaving. The following are examples of approaches reducing access to lethal means for persons at-risk of suicide:
  - *Intervening at Suicide Hotspots.* Suicide hotspots, or places where suicides may take place relatively easily, include tall structures (e.g., bridges, cliffs, balconies, and rooftops), railway tracks, and isolated locations such as parks. Efforts to prevent suicide at these locations include erecting barriers or limiting access to prevent jumping, and installing signs and telephones to encourage individuals who are considering suicide, to seek help.<sup>100</sup>

- *Safe Storage Practices.* Safe storage of medications, firearms, and other household products can reduce the risk for suicide by separating vulnerable individuals from easy access to lethal means. Such practices may include education and counseling around storing firearms locked in a secure place (e.g., in a gun safe or lock box), unloaded and separate from the ammunition; and keeping medicines in a locked cabinet or other secure location away from people who may be at risk or who have made prior attempts.<sup>89,101</sup>
- **Organizational policies and culture** that promote protective environments may be implemented in places of employment, detention facilities, and other secured environments (e.g. residential settings). Such policies and cultural values encourage leadership from the top down and may promote prosocial behavior (e.g., asking for help), skill building, positive social norms, assessment, referral and access to helping services (e.g., mental health, substance abuse treatment, financial counseling), and development of crisis response plans, postvention and other measures to foster a safe physical environment. Such policies and cultural shifts can positively impact organizational climate and morale and help prevent suicide and its related risk factors (e.g. depression, social isolation).<sup>88,102</sup>
- **Community-based policies to reduce excessive alcohol use.** Research studies in the United States have found that greater alcohol availability is positively associated with alcohol-involved suicides.<sup>103-105</sup> Policies to reduce excessive alcohol use broadly include zoning to limit alcohol outlet locations and density, taxes on alcohol, and bans on the sale of alcohol for individuals under the legal drinking age.<sup>105</sup> These policies are important because acute alcohol use has been found to be associated with more than one-third of suicides and approximately 40% of suicide attempts.<sup>106</sup>

### Potential Outcomes

- Increases in safe storage of lethal means
- Reductions in rates of suicide
- Reductions in suicide attempts
- Increases in help-seeking
- Reductions in alcohol-related suicide deaths

### Evidence

The evidence suggests that creating protective environments can reduce suicide and suicide attempts and increase protective behaviors.

- **Reduce access to lethal means among persons at-risk of suicide.** A meta-analysis examining the impact of *suicide hotspot interventions* implemented in combination or in isolation, both in the U.S. and abroad, found associated reduced rates of suicide.<sup>100,107</sup> For example, after erecting a barrier on the Jacques-Cartier bridge in Canada, the suicide rate from jumping from the bridge decreased from about 10 suicide deaths per year to about 3 deaths per year.<sup>108</sup> Moreover, the reduction in suicides by jumping was sustained even when all bridges and nearby jumping sites were considered, suggesting little to no displacement of suicides to other jumping sites.<sup>108</sup> Further evidence for the effectiveness of bridge barriers was demonstrated by a study examining the impact of the *removal* of safety barriers from the Grafton Bridge in Auckland, New Zealand. After removal of the barrier, both the number and rate of suicide increased five-fold.<sup>93,109</sup>

Another form of means reduction involves implementation of *safe storage practices*. In a case-control study of firearm-related events identified from 37 counties in Washington, Oregon, and Missouri, and from 5 trauma centers, researchers found that storing firearms unloaded, separate from ammunition, in a locked place or secured with a safety device was protective of suicide attempts among adolescents.<sup>110</sup> Further, a recent systematic review of clinic and community-based education and counseling interventions suggested that the provision of safety devices significantly increased safe firearm storage practices compared to counseling alone or compared to the provision of economic incentives to acquire safety devices on one's own.<sup>101</sup>

Another program, the *Emergency Department Counseling on Access to Lethal Means (ED CALM)*, trained psychiatric emergency clinicians in a large children's hospital to provide lethal means counseling and safe storage boxes to parents of patients under age 18 receiving care for suicidal behavior. In a pre-post quality improvement project, Runyan et al<sup>89</sup> found that at post-test 76% (of the 55% of parents followed up, n=114) reported that all medications in the home were locked up as compared to fewer than 10% at the time of the initial emergency department visit. Among parents who indicated the presence of guns in the home at pre-test (i.e., 67%), all (100%) reported guns were currently locked up at post-test.<sup>89</sup>

- **Organizational policies and culture.** *Together for Life* is a workplace program of the Montreal Police Force implemented to address suicide among officers. Policy and program components were designed to foster an organizational culture that promoted mutual support and solidarity among all members of the Force. The program included training of supervisors, managers and all units to improve competencies in identifying suicidal risk and to improve use and awareness of existing resources. The program also included an education campaign to improve awareness and help-seeking.<sup>111</sup> Police suicides were tracked over 12 years and compared to rates in the control city of Quebec. The suicide rate in the intervention group decreased significantly by 78.9% to a rate of 6.4 suicides per 100,000 population per year compared to an 11% increase in the control city (29.0 per 100,000).<sup>111</sup>

Another example of this approach is the *United States Air Force Suicide Prevention Program*. The program included 11 policy and education initiatives and was designed to change the culture of the Air Force surrounding suicide. The program uses leaders as role models and agents of change, establishes expectations for behavior related to awareness of suicide risk, develops population skills and knowledge (i.e., education and training), and investigates every suicide (i.e., outcomes measurement). The program represents a fundamental shift from viewing suicide and mental illness solely as medical problems and instead sees them as larger service-wide problems impacting the whole community.<sup>112</sup> Using a time-series design to examine the impact of the program on various violence-related outcomes, researchers found that the program was associated with a 33% relative risk reduction in suicide.<sup>112</sup> The program was also associated with relative risk reductions in related outcomes including moderate and severe family violence (30% and 54%, respectively), homicide (51%), and accidental death (18%).<sup>112</sup> A longitudinal assessment of the program over the period 1981 to 2008 (16 years before the 1997 launch of the program and 11 years post-launch) found significantly lower rates of suicide after the program was launched than before.<sup>87</sup> These effects were sustained over time, except in 2004, which the authors found was associated with less rigorous implementation of program components in that year than in the other years.<sup>87</sup>

Finally, while the evidence is still being built for suicide prevention in correctional facilities, preliminary evidence suggests organizational policies and practices that include routine suicide prevention training for all staff; standardized intake screening and risk assessment; provision of shared information between staff members (especially in transitioning or transferring of inmates); varying levels of observation; safe physical environment; emergency response protocols; notification of suicidal behavior/suicide through the chain of command; and critical incident stress debriefing and death review can potentially reduce suicide.<sup>102</sup> When these policies and practices were implemented across 11 state prisons in Louisiana, suicide rates dropped 46%, from a rate of 23.1 per 100,000 before the intervention to 12.4 per 100,000 the following year.<sup>113</sup> Other similar programs have seen declines in suicide both in the United States and internationally.<sup>114</sup>

- **Community-based policies to reduce excessive alcohol use.** While multiple policies to limit excessive use of alcohol exist, several studies on alcohol outlet density and risk factors for suicide, such as interpersonal violence and social connectedness,<sup>115-118</sup> suggest that measures to reduce alcohol outlet density can potentially reduce alcohol-involved suicides. Additionally, a longitudinal analysis of alcohol outlet density, suicide mortality, and hospitalizations for suicide attempts over 6 years in 581 California zip codes indicated that greater density of bars, specifically, is related to greater suicide and suicide attempts, particularly in rural areas.<sup>119</sup>

## Promote Connectedness

### Rationale

Sociologist, Emile Durkheim theorized in 1897 that weak social bonds, i.e., lack of connectedness, are among the chief causes for suicidality.<sup>120</sup> Connectedness is the degree to which an individual or group of individuals are socially close, interrelated, or share resources with others.<sup>121</sup> Social connections can be formed within and between multiple levels of the social ecology,<sup>17</sup> for instance between individuals (e.g., peers, neighbors, co-workers), families, schools, neighborhoods, workplaces, faith communities, cultural groups, and society as a whole. Related to connectedness, social capital refers to a sense of trust in one's community and neighborhood, social integration, and also the availability and participation in social organizations.<sup>122,123</sup> Many ecological cross-sectional and longitudinal studies have examined the impact of aspects of social capital on depression symptoms, depressive disorder, mental health more generally, and suicide. While the evidence is limited, existing studies suggest a positive association between social capital (as measured by social trust and community/neighborhood engagement), and improved mental health.<sup>124,125</sup> Connectedness and social capital together may protect against suicidal behaviors by decreasing isolation, encouraging adaptive coping behaviors, and by increasing belongingness, personal value, and worth, to help build resilience in the face of adversity. Connectedness can also provide individuals with better access to formal supports and resources, mobilize communities to meet the needs of its members and provide collective primary prevention activities to the community as a whole.<sup>121</sup>

### Approaches

Promoting connectedness among individuals and within communities through modeling peer norms and enhancing community engagement may protect against suicide.

- **Peer norm programs** seek to normalize protective factors for suicide such as help-seeking, reaching out and talking to trusted adults, and promote peer connectedness. By leveraging the leadership qualities and social influence of peers, these approaches can be used to shift group-level beliefs and promote positive social and behavioral change. These approaches typically target youth and are delivered in school settings but can also be implemented in community settings.<sup>126</sup>
- **Community engagement activities.** Community engagement is an aspect of social capital.<sup>127</sup> Community engagement approaches may involve residents participating in a range of activities, including religious activities, community clean-up and greening activities, and physical exercise. These activities provide opportunities for residents to become more involved in the community and to connect with other community members, organizations, and resources, resulting in enhanced overall physical health, reduced stress, and decreased depressive symptoms, thereby reducing risk of suicide.

## Potential Outcomes

- Increases in healthy coping attitudes and behaviors
- Increases in referrals for youth in distress
- Increases in help-seeking behaviors
- Increases in positive perceptions of adult support

## Evidence

Current evidence suggests a number of positive benefits of peer norm and community engagement activities, although more evaluation research is needed to examine whether these improvements in factors that protect against suicidal behavior translate into reduced suicide attempts and deaths.

- **Peer norm programs.** Evaluations show that programs such as *Sources of Strength* can improve school norms and beliefs about suicide that are created and disseminated by student peers. In a randomized controlled trial of *Sources of Strength* conducted with 18 high-schools (6 metropolitan, 12 rural), researchers found that the program improved adaptive norms regarding suicide, connectedness to adults, and school engagement.<sup>36</sup> Peer leaders were also more likely than controls to refer a suicidal friend to an adult. For students, the program resulted in increased perceptions of adult support for suicidal youths, particularly among those with a history of suicidal ideation, and the acceptability of help-seeking behaviors. Finally, trained peer leaders also reported a greater decrease in maladaptive coping attitudes compared with untrained leaders.<sup>36</sup>
- **Community engagement activities.** A vacant lot greening initiative was undertaken in Philadelphia between 1999 and 2008. Local residents and community members worked together to green 4,436 lots (or 7.8 million square feet) in 4 areas of the city. Researchers found significant reductions in community residents' self-reported level of stress, which is a risk factor for suicide, and engagement in more physical exercise, a protective factor for suicide, than residents in control vacant lot areas. There is some evidence for other cross-cutting benefits, including reductions in firearm assaults and vandalism.<sup>128,129</sup>

## Teach Coping and Problem-Solving Skills

### Rationale

Building life skills prepares individuals to successfully tackle every day challenges and adapt to stress and adversity. Life skills encompasses many concepts, but most often include coping and problem-solving skills, emotional regulation, conflict resolution, and critical thinking. Life skills are important in shielding individuals from suicidal behaviors.<sup>126</sup> Suicide prevention programs that focus on life and social skills training are drawn from social cognitive theories,<sup>130</sup> surmising that suicidal behavior is attributed to either direct learning and modeling or environmental and individual (e.g. hopelessness) characteristics. The inability to employ adequate strategies to cope with immediate stressors or identify and find solutions for problems has been characterized among suicide attempters.<sup>131</sup> Teaching and providing youth with the skills to tackle every day challenges and stressors is, therefore, an important developmental component to suicide prevention.

### Approaches

Social-emotional learning programs and parenting skill and family relationship programs are two approaches for teaching coping and problem-solving skills.

- **Social-emotional learning programs** focus on developing and strengthening communication and problem-solving skills, emotion regulation, conflict resolution, help seeking and coping skills. These approaches address a range of risk and protective factors for suicidal behavior. They provide children and youth with skills to resolve problems in relationships, school, and with peers, and help youth to address other negative influences (e.g., substance use) associated with suicide.<sup>126</sup> These approaches are typically delivered to all students in a particular grade or school, although some programs also focus on groups of students considered to be at high risk for suicide. Opportunities to practice and reinforce skills are an important part of programs that work.<sup>132</sup>
- **Parenting skill and family relationship programs** provide caregivers with support and are designed to strengthen parenting skills, enhance positive parent-child interactions, and improve children's behavioral and emotional skills and abilities.<sup>132</sup> Programs are typically designed for parents or caregivers with children in a specific age range and can be self-directed or delivered to individual families or groups of families. Some programs have sessions primarily with parents or caregivers while others include sessions for parents or caregivers, youth, and the family. Specific program content typically varies by the age of the child but often has consistent themes of child development, parent-child communication and relationships, and youth's interpersonal and problem-solving skills.

## Potential Outcomes

- Reductions in suicide ideation
- Reductions in suicide attempts
- Reductions in suicide risk behaviors (i.e., depression, anxiety, conduct problems, substance abuse)
- Improvements in help-seeking behavior
- Improvements in social competence and emotional regulation skills
- Improvements in problem-solving and conflict management skills

## Evidence

Several social-emotional learning and parenting and family relationship programs have been shown in rigorous evaluations to improve resilience and reduce problem behavior and risk factors for various behaviors, including ones closely related to suicide, such as depression, internalizing behaviors, and substance abuse.<sup>133</sup>

- **Social-emotional learning programs.** The *Youth Aware of Mental Health Program (YAM)* is a program developed for teenagers aged 14-16 that uses interactive dialogue and role-playing to teach adolescents about the risk and protective factors associated with suicide (including knowledge about depression and anxiety) and enhances their problem-solving skills for dealing with adverse life events, stress, school and other problems.<sup>134</sup> In a cluster-randomized controlled trial conducted across 10 European Union countries and 168 schools, students in schools randomized to *YAM* were significantly less likely to attempt suicide and have severe suicidal ideation at the 12-month follow-up compared to students in control schools which received educational materials and care as usual. Overall, the relative risk of youth suicide attempts among the *YAM* group was reduced by over 50% demonstrating that out of 1000 students, five attempted suicide in the *YAM* group compared to 11 in the control group. Additionally, related to severe suicide ideation, in the *YAM* group, relative risk fell by 49.6%.<sup>134</sup>

Another example is the *Good Behavior Game (GBG)*, which is a classroom-based program for elementary school children aged 6-10. The program uses a team-based behavior management strategy that promotes good behavior by setting clear expectations for good behavior and consequences for maladaptive behavior. The goal of the *GBG* program is to create an integrated classroom social system that is supportive of all children being able to learn with little aggressive or disruptive behavior.<sup>135</sup> Two cohorts of youths participated in the program in 1985-86 and 1986-87 school years when they were in the first and second grades. A number of proximal and distal outcomes were assessed among the two cohorts over time. With respect to distal suicide-related outcomes, an outcome evaluation of the *GBG* indicated that individuals in the first cohort who were assigned to participate in *GBG* when

they were in the first grade reported half the adjusted odds of suicidal ideation and suicide attempts when assessed approximately 15 years later, between the ages of 19 to 21, compared to peers who had been in a standard classroom setting. The beneficial effect of the program was consistent for suicidal ideation regardless of whether baseline covariates were included.<sup>135</sup> The *GBG* effect on attempts was less robust in some adjusted models including caregiver mental health. In the second cohort of *GBG* students, neither suicidal ideation nor suicide attempts were significantly different between *GBG* and the control interventions.<sup>135</sup> The researchers believed this may have been due to a lack of implementation fidelity, including less mentoring and monitoring of teachers. *GBG* was also found to be associated with reduced risk of later substance abuse and other suicide risk factors among the first cohort of students. Results for the second cohort were generally smaller but in the desired direction.<sup>136</sup>
